SSerxhs 的 ICPC 模板

SSerxhs

2025 年 1 月 15 日

ver: 3.9.16

目录

1 前言

此模板的初衷是个人使用，因此已有的模板可能未列出。建议结合 Heltion 模板和 HDU 模板使用。

模板需要的版本为 cpp17 或 cpp20。

大部分情况下，涉及取模的都需要使用 `unsigned long long`，即使类型名是 `ll`。这是因为值域较大有利于合理减少取模次数。

`optional` 的用法：一个 `optional` 变量 `r` 可以用 `if (r)` 判断其是否有值。取出值的方法是 `*r`。常见于包含无解又包含空集解的代码中，便于区分无解和空集解。

常见的被漏掉的初始代码：

```
#define all(x) (x).begin(),(x).end()
using lll=__int128;
template<class T1, class T2> bool cmin(T1 &x, const T2 &y) { if (y<x) { x=y; return 1; } return
    0; }
template<class T1, class T2> bool cmax(T1 &x, const T2 &y) { if (x<y) { x=y; return 1; } return
    0; }
template<class typC> void read(typC &x)
{
    int c=getchar(),fh=1;
    while ((c<48)||(c>57))
    {
        if (c=='-') {c=getchar();fh=-1;break;}
        c=getchar();
    }
    x=c^48;c=getchar();
    while ((c>=48)&&(c<=57))
    {
        x=x*10+(c^48);
        c=getchar();
    }
    x*=fh;
}
```

常见的缺漏算法：

回文自动机。

2 数据结构

2.1 树状数组

支持单点修改、求前缀和、二分前缀和大于等于 x 的第一个位置。

二分这部分没有验证过。

```
template<typename typC> struct bit
{
    vector<typC> a;
    int n;
    bit() { }
    bit(int nn):n(nn), a(nn+1) { }
    template<typename T> bit(int nn, T *b):n(nn), a(nn+1)
    {
        for (int i=1; i<=n; i++) a[i]=b[i];
        for (int i=1; i<=n; i++) if (i+(i&-i)<=n) a[i+(i&-i)]+=a[i];
    }
    void add(int x, typC y)
    {
        //cerr<<"add "<<x<<" by "<<y<<endl;
        assert(1<=x&&x<=n);
        a[x]+=y;
        while ((x+=x&-x)<=n) a[x]+=y;
    }
    typC sum(int x)
    {
        //cerr<<"sum "<<x;
        assert(0<=x&&x<=n);
        typC r=a[x];
        while (x^=x&-x) r+=a[x];
        //cerr<<"= "<<r<<endl;
        return r;
    }
    typC sum(int x, int y)
    {
        return sum(y)-sum(x-1);
    }
    int lower_bound(typC x)
    {
        if (n==0) return 0;
        int i=__lg(n), j=0;
        for (; i>=0; i--) if ((1<<i|j)<=n&&a[1<<i|j]<x) j|=1<<i, x-=a[j];
        return j+1;
    }
};
```

2.2 线段树

包含标记的线段树，支持线段树上二分，采用左闭右闭。但只支持求左侧第一个符合条件的下标。

要求：具有 info+info，info+=tag，tag+=tag。info，tag 需要有默认构造，但不必有正确的值。

```
template<class info, class tag> struct sgt
```

```
{
    int n, shift;
    info *a;
    info tmp;
    vector<info> s;
    vector<tag> tg;
    vector<int> lz;
    bool flg;
    void build(int x, int l, int r)
    {
        if (l==r)
        {
            s[x]=(flg?tmp:a[l]);
            return;
        }
        int c=x*2, m=l+r>>1;
        build(c, l, m); build(c+1, m+1, r);
        s[x]=s[c]+s[c+1];
    }
    sgt(info *b, int L, int R):n(R-L+1), shift(L-1), a(b+L-1), s(R-L+1<<2), tg(R-L+1<<2), lz(R-L
        +1<<2)
    {
        flg=0;
        build(1, 1, n);
    }//[L,R]
    sgt(info b, int L, int R):n(R-L+1), shift(L-1), s(R-L+1<<2), tg(R-L+1<<2), lz(R-L+1<<2)
    {
        tmp=b;
        flg=1;
        build(1, 1, n);
    }//[L,R]
    int z, y;
    info res;
    tag dt;
    bool fir;
private:
    void _modify(int x, int l, int r)
    {
        if (z<=l&&r<=y)
        {
            s[x]+=dt;
            if (lz[x]) tg[x]+=dt; else tg[x]=dt;
            lz[x]=1;
            return;
        }
        int c=x*2, m=l+r>>1;

        find_right_most(1, 1, n);
        return {z+shift, res};
    }
};
```

2.3 哈希表

支持如同 `map` 一样使用 `[]` 访问。`default` 指的是未赋值情形的值。新版本未验证。

```
template<class Tx,class Ty> struct hashtable //定义域, 值域
{
```

```
    const static int N=2e6+5,p=1e6+7;//元素个数，模数
    Tx X[N];
    Ty Y[N],val;
    int fir[p],nxt[N],sz,cnt;
    ht(Ty val=Ty{}):val(val),sz(0),cnt(0){memset(fir,-1,sizeof fir);}
    Ty &operator[](T x)
    {
        int index=(x%p+p)%p;
        for (int i=fir[index];i!=-1;i=nxt[i]) if (X[i]==x) return Y[i];//若 x 不重复，可以省略这个
            for
        X[cnt]=x;
        Y[cnt]=val;
        nxt[cnt]=fir[index];
        fir[index]=cnt++;
        return Y[cnt-1];
    }
    void clear()
    {
        cnt=0;
        while (sz) fir[((X[--sz])%p+p)%p]=0;
    }
    void iterate()//遍历。用于自行修改
    {
        for (int i=0;i<sz;i++)
        {
            T x=X[i];
            TT y=Y[i];
            //(x,y)
        }
    }
};
```

2.4 珂朵莉树

支持区间赋值、单点访问。维护每个连续段的范围和值。

如果希望维护所有连续段的整体信息（如长度的最大值），修改 add 和 del 函数即可，分别表示连续段被加入和被删去。

特别注意一开始 insert 的不会触发 add，只有 modify 会触发。

```
namespace chtholly_tree
{
    using T=int;//可以把 T 修改为任意想要的类型。
    struct node
    {
        int l;
        mutable int r;
        mutable T v;
        int len() const { return r-l+1; }
        bool operator<(const node &x) const { return l<x.l; }
    };
    void add(const node &a) {}
    void del(const node &a) {}
    class odt: public set<node>
    {
    public:
        typedef odt::iterator iter;
```

```
        iter split(int x)
        {
            iter it=lower_bound({x});
            if (it!=end()&&it->l==x) return it;
            node t=*--it,a={t.l,x-1,t.v},b={x,t.r,t.v};
            del(*it); add(a); add(b);
            erase(it); insert(a);
            return insert(b).first;
        }
        void modify(int l,int r,T v)//[l,r]
        {
            iter lt,rt,it;
            rt=r==rbegin()->r?end():split(r+1); lt=split(l);//[lt,rt)
            while (lt!=begin()&&(it=prev(lt))->v==v) l=(lt=it)->l;
            while (rt!=end()&&rt->v==v) r=(rt++)->r;
            for (it=lt; it!=rt; it++) del(*it);
            add({l,r,v});
            erase(lt,rt); insert({l,r,v});
        }
        T operator[](const int x) const { return prev(upper_bound({x}))->v; }//直接访问单点
        iter find(int x) const {return prev(upper_bound({x}));}//找到对应的线段
    };
}
using chtholly_tree::node,chtholly_tree::odt;
typedef odt::iterator iter;
int main()
{
    odt s;
    s.insert({0,5,1});  // 先 insert({L,R,x}) 表示整个下标范围和初始值。 左闭右闭。
                       // s={1,1,1,1,1,1}
    s.modify(2,3,2);  // 左闭右闭。s={1,1,2,2,1,1}
    for (auto [l,r,v]:s)
    {
        //(l,r,v)=(0,1,1)
        //(l,r,v)=(2,3,2)
        //(l,r,v)=(4,5,1)
    }
}
```

2.5 带删堆

本质是额外维护一个堆 q 表示要被删除的元素，当 p 的最值和 q 一样时删除。
需要保证每次 pop 的元素都存在于堆中。
本代码的用法和 priority_queue 一致。

```
template<class T, class T1=vector<T>, class T2=less<T>> struct heap
{
private:
    priority_queue<T, T1, T2> p, q;
public:
    void push(const T &x)
    {
        if (!q.empty()&&q.top()==x)
        {
            q.pop();
            while (!q.empty()&&q.top()==p.top()) p.pop(), q.pop();
```

```
        }
        else p.push(x);
    }
    void pop()
    {
        p.pop();
        while (!q.empty()&&p.top()==q.top()) p.pop(), q.pop();
    }
    void pop(const T &x)
    {
        if (p.top()==x)
        {
            p.pop();
            while (!q.empty()&&p.top()==q.top()) p.pop(), q.pop();
        }
        else q.push(x);
    }
    T top() const { return p.top(); }
    int size() const { return p.size()-q.size(); }
    bool empty() const { return p.empty(); }
    vector<T> to_vector() const
    {
        vector<T> a;
        auto P=p, Q=q;
        while (P.size())
        {
            a.push_back(P.top()); P.pop();
            while (Q.size()&&P.top()==Q.top()) P.pop(), Q.pop();
        }
        return a;
    }
};
```

2.6 前 k 大的和

本质是用小根堆维护前 k 大的数，用大根堆维护其余数。

如果需要支持删除，结合前面一个使用，或者直接用 `multiset` 进行 `extract`。

为了方便起见，直接给出支持删除的版本，并且使用 `long long`。如果不需要支持删除，类型改为优先队列并去掉 `pop` 函数即可。

注意：复杂度为 $O(k-k')$，其中 k' 是上一次询问的 k。也就是说，多组询问时询问的 k 的差值应该尽可能小。

其用法与 `priority_queue` 保持一致，可以用同样的方法改写成前 k 小。

```
using ll=long long;
template<class T, class T1=vector<T>, class T2=less<T>> struct ksum_pop
{
private:
    struct __cmp
    {
        bool operator()(const T &x, const T &y) const
        {
            return x!=y&&!T2()(x, y);
        }
    };
    heap<T, T1, __cmp> p;
```

```
    heap<T, T1, T2> q;
    ll cur;
public:
    ksum_pop():cur(0) { }
    void push(const T &x)
    {
        if (!q.size()||!T2()(x, q.top())) p.push(x), cur+=x; else q.push(x);
    }
    int size() const { return p.size()+q.size(); }
    void pop(const T &x)
    {
        if (q.size()&&!T2()(q.top(), x)) q.pop(x);
        else p.pop(x), cur-=x;
    }
    ll sum(int k)
    {
        while (p.size()<k)
        {
            cur+=q.top();
            p.push(q.top());
            q.pop();
        }
        while (p.size()>k)
        {
            cur-=p.top();
            q.push(p.top());
            p.pop();
        }
        return cur;
    }
};
```

2.7 可持久化数组

历史遗留产物，无意义，仅作留存，不会更新。

$O((n+q)\log(n))$，$O((n+q)\log(n))$。

```
struct arr
{
    int c[M][2],rt[0],s[M],b[N];
    int ds,n,ver,v,p,i;
    void build(int &x,int l,int r)
    {
        x=++ds;
        if (l==r) {s[x]=b[l];return;}
        build(c[x][0],l,l+r>>1);
        build(c[x][1],(l+r>>1)+1,r);
    }
    void rebuild(int &x,int pre)
    {
        x=++ds;int l=1,r=n,mid,now=x;
        while (l<r)
        {
            mid=l+r>>1;
            if (mid>=p){c[now][1]=c[pre][1];now=c[now][0]=++ds;r=mid;pre=c[pre][0];} else {c[now
                ][0]=c[pre][0];now=c[now][1]=++ds;l=mid+1;pre=c[pre][1];}
```

```
        }
        s[now]=v;
    }
    void init(int *a,int nn)
    {
        n=nn;
        for (i=1;i<=n;i++) b[i]=a[i];
        build(rt[0],1,n);
    }
    int mdf(int pv,int pos,int val)
    {
        p=pos,v=val;
        rebuild(rt[++ver],rt[pv]);
        return ver;
    }
    int ask(int ve,int pos)
    {
        int l=1,r=n,x=rt[ve],mid;
        rt[++ver]=rt[ve];
        while (l<r)
        {
            mid=l+r>>1;
            if (mid>=pos) {x=c[x][0];r=mid;} else {x=c[x][1];l=mid+1;}
        }
        return s[x];
    }
};
```

2.8 左偏树/可并堆

建议不要使用。pb_ds 可以替代这个功能。我完全没有使用过这个板子。

$O((n+q)\log n)$，$O(n)$。

```
struct left_tree//小根堆，大根堆需要改的地方注释了
{
    int jl[N],v[N],f[N],c[N][2],tf[N],n;//tf只有删非堆顶才用
    bool ed[N];
    void init(const int nn,const int *a)
    {
        jl[0]=-1;n=nn;
        memset(jl+1,0,n<<2);
        memset(tf+1,0,n<<2);//同上
        memset(c+1,0,n<<3);
        memset(ed+1,0,n);
        for (int i=1;i<=n;i++) v[f[i]=i]=a[i];
    }
    int mg(int x,int y)
    {
        if (!(x&&y)) return x|y;
        if (v[x]>v[y]||v[x]==v[y]&&x>y) swap(x,y);//改
        tf[c[x][1]=mg(c[x][1],y)]=x;//同上
        if (jl[c[x][0]]<jl[c[x][1]]) swap(c[x][0],c[x][1]);
        jl[x]=jl[c[x][1]]+1;
        return x;
    }
    int getf(int x)
```

```
    {
        if (f[x]==x) return x;
        return f[x]=getf(f[x]);
    }
    int merge(int x,int y)
    {
        if (ed[x]||ed[y]||(x=getf(x))==(y=getf(y))) return x;
        int z=mg(x,y);return f[x]=f[y]=z;
    }
    int getv(int x)//需要自行判断是否存在
    {
        return v[getf(x)];
    }
    int del(int x)//删除堆内最值
    {
        tf[c[x][0]]=tf[c[x][1]]=0;
        f[c[x][0]]=f[c[x][1]]=f[x]=mg(c[x][0],c[x][1]);
        ed[x]=1;c[x][0]=c[x][1]=tf[x]=0;return f[x];
    }
    int del_all(int x)//删除堆内非最值（没验证过）
    {
        int fa=tf[x];
        if (f[c[x][0]]==x) f[c[x][0]]=getf(tf[x]);
        if (f[c[x][1]]==x) f[c[x][1]]=f[tf[x]];
        tf[x]=tf[c[x][0]]=tf[c[x][1]]=0;
        tf[c[fa][c[fa][1]==x]=mg(c[x][0],c[x][1])]=fa;
        c[x][0]=c[x][1]=0;
        while (jl[c[fa][0]]<jl[c[fa][1]])
        {
            swap(c[fa][0],c[fa][1]);
            jl[fa]=jl[c[fa][1]]+1;
            fa=tf[fa];
        }
    }
    void out(int n)
    {
        for (int i=1;i<=n;i++) printf("%d: c%d&%d f%d v%d\n",i,c[i][0],c[i][1],f[i],v[i]);
    }
};
```

2.9 树状数组区间加区间求和

本质：a_n 区间加等价于差分数组 d_n 的单点加。

$\sum_{i=1}^{m} a_i = \sum_{i=1}^{m}\sum_{j=1}^{i} d_j = \sum_{j=1}^{m} d_j(m-j+1) = ((m+1)\sum_{j=1}^{m} d_j) - (\sum_{j=1}^{m} jd_j)$。

分别维护 d_j 和 jd_j 的前缀和。

$O(n) \sim O(q\log n)$，$O(n)$。

```
struct bit
{
    ll a[N],b[N],s[N];//有初始值
    int n;
    void init(int nn,int *a)//初始值
    {
        n=nn;s[0]=0;
        for (int i=1;i<=n;i++) s[i]=s[i-1]+a[i];
```

```
    }
    void mdf(int l,int r,ll dt)
    {
        int i;++r;
        ll j=dt*l;
        a[l]+=dt;b[l]+=j;
        while ((l+=l&-l)<=n)
        {
            a[l]+=dt;
            b[l]+=j;
        }
        if (r<=n)
        {
            j=dt*r;
            a[r]-=dt;b[r]-=j;
            while ((r+=r&-r)<=n)
            {
                a[r]-=dt;
                b[r]-=j;
            }
        }
    }
    ll presum(int x)
    {
        ll r=a[x],rr=b[x];
        int y=x;
        while (x^=x&-x)
        {
            r+=a[x];
            rr+=b[x];
        }
        return r*(y+1)-rr+s[y];
    }
    ll sum(int l,int r)
    {
        return presum(r)-presum(l-1);
    }
};
```

2.10 二维树状数组矩形加矩形求和

本质还是差分，只不过这次要维护 $d_{i,j}, d_{i,j}i, d_{i,j}j, d_{i,j}ij$。

$O(n^2) \sim O(q\log^2 n)$，$O(n^2)$

```
struct bit2
{
    ll a[2050][2050],b[2050][2050],c[2050][2050],d[2050][2050];
    int n,m;
    private:
    void cha(ll a[][2050],int x,int y,int z)
    {
        int i,j;
        for (i=x;i<=n;i+=(i&(-i))) for (j=y;j<=m;j+=(j&(-j))) a[i][j]+=z;
    }
    ll he(int x,int y)
    {
```

```
        if ((x<=0)||(y<=0)) return 0;
        int i,j;
        ll z=0,w=0;
        for (i=x;i;i-=(i&(-i))) for (j=y;j;j-=(j&(-j))) z+=a[i][j];
        z*=(x+1)*(y+1);
        w=0;
        for (i=x;i;i-=(i&(-i))) for (j=y;j;j-=(j&(-j))) w+=b[i][j];
        z-=w*(y+1);
        w=0;
        for (i=x;i;i-=(i&(-i))) for (j=y;j;j-=(j&(-j))) w+=c[i][j];
        z-=w*(x+1);
        for (i=x;i;i-=(i&(-i))) for (j=y;j;j-=(j&(-j))) z+=d[i][j];
        return z;
    }
    public:
    void init(int x,int y)
    {
        n=x;m=y;
    }
    void add(int u,int v,int x,int y,int z)//(x1,y1,x2,y2,dt)
    {
        cha(a,u,v,z);
        cha(b,u,v,u*z);//小心乘爆
        cha(c,u,v,v*z);
        cha(d,u,v,u*v*z);
        ++x;++y;
        if (x<=n)
        {
            cha(a,x,v,-z);
            cha(b,x,v,-z*x);
            cha(c,x,v,-z*v);
            cha(d,x,v,-z*x*v);
        }
        if (y<=m)
        {
            cha(a,u,y,-z);
            cha(b,u,y,-z*u);
            cha(c,u,y,-z*y);
            cha(d,u,y,-z*u*y);
            if (x<=n)
            {
                cha(a,x,y,z);
                cha(b,x,y,z*x);
                cha(c,x,y,z*y);
                cha(d,x,y,z*x*y);
            }
        }
    }
    ll sum(int u,int v,int x,int y)//(x1,y1,x2,y2)
    {
        --u;--v;
        return (he(x,y)+he(u,v)-he(u,y)-he(x,v));
    }
};
```

2.11 带修莫队（功能：区间数有多少种不同的数字）

按照 $n^{\frac{2}{3}}$ 分块，排序关键字是 l,r,t 所在的块（t 是版本号，每次修改都会增加一个版本），可以奇偶分块优化。

相比于传统莫队多了一个 modify。

$O(n^{\frac{5}{3}})$，$O(n)$。

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
#define all(x) (x).begin(),(x).end()
const int N=1.4e5,M=1e6+2;
int a[N],ans[N],bel[N],cnt[M],sum,z,y,cur;
struct P
{
    int p,v;
};
struct Q
{
    int l,r,t,p;
    bool operator<(const Q &o) const
    {
        if (bel[l]!=bel[o.l]) return bel[l]<bel[o.l];
        if (bel[r]!=bel[o.r]) return (bel[l]&1)^bel[r]<bel[o.r];
        return (bel[r]&1)?t<o.t:t>o.t;
    }
};
Q b[N];
P d[N];
void add(const int &x) {sum+=!(cnt[a[x]]++);}
void del(const int &x) {sum-=!(--cnt[a[x]]);}
void mdf(const int &x)
{
    auto &[p,v]=d[x];
    if (z<=p&&p<=y) del(p);
    swap(a[p],v);
    if (z<=p&&p<=y) add(p);
}
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    int n,m,q1=0,q2=0,i,ksiz;
    cin>>n>>m;
    for (i=1;i<=n;i++) cin>>a[i];
    for (i=1;i<=m;i++)
    {
        char c;
        int l,r;
        cin>>c>>l>>r;
        if (c=='Q') ++q1,b[q1]={l,r,q2,q1};
        else d[++q2]={l,r};
    }
    ksiz=max(1.0,round(cbrt((ll)n*n)));
    for (i=1;i<=n;i++) bel[i]=i/ksiz;
    sort(b+1,b+q1+1);
    z=b[1].l;y=z-1;cur=0;
    for (i=1;i<=q1;i++)
```

```
    {
        auto [l,r,t,p]=b[i];
        while (z>l) add(--z);
        while (y<r) add(++y);
        while (z<l) del(z++);
        while (y>r) del(y--);
        while (cur<t) mdf(++cur);
        while (cur>t) mdf(cur--);
        ans[p]=sum;
    }
    for (i=1;i<=q1;i++) cout<<ans[i]<<'\n';
}
```

2.12 二次离线莫队

直接摘录题解，用途不大。

$O(n\sqrt{n})$，$O(n)$。

珂朵莉给了你一个序列 a，每次查询给一个区间 $[l,r]$，查询 $l \le i < j \le r$，且 $a_i \oplus a_j$ 的二进制表示下有 k 个 1 的二元组 (i,j) 的个数。$\oplus$ 是指按位异或。

二次离线莫队，通过扫描线，再次将更新答案的过程离线处理，降低时间复杂度。假设更新答案的复杂度为 $O(k)$，它将莫队的复杂度从 $O(nk\sqrt{n})$ 降到了 $O(nk+n\sqrt{n})$，大大简化了计算。设 x 对区间 $[l,r]$ 的贡献为 $f(x,[l,r])$，我们考虑区间端点变化对答案的影响：以 $[l..r]$ 变成 $[l..(r+k)]$ 为例，$\forall x \in [r+1,r+k]$ 求 $f(x,[l,x-1])$。我们可以进行差分：$f(x,[l,x-1]) = f(x,[1,x-1]) - f(x,[1,l-1])$，这样转化为了一个数对一个前缀的贡献。保存下来所有这样的询问，从左到右扫描数组计算就可以了。但是这样做，空间是 $O(n\sqrt{n})$ 的，不太优秀，而且时间常数巨大。。这样的贡献分为两类：

1. 减号左边的贡献永远是一个前缀和它后面一个数的贡献。这可以预处理出来。2. 减号右边的贡献对于一次移动中所有的 x 来说，都是不变的。我们打标记的时候，可以只标记左右端点。

这样，减小时间常数的同时，空间降为了 $O(n)$ 级别。是一个很优秀的算法了。处理前缀询问的时候，我们利用异或运算的交换律，即 $a \text{ xor } b = c \iff a \text{ xor } c = b$ 开一个桶 t，$t[i]$ 表示当前前缀中与 i 异或有 k 个数位为 1 的数有多少个。则每加入一个数 $a[i]$，对于所有 $\text{popcount}(x) = k$ 的 x，$t[a[i] \text{ xor } x] \leftarrow t[a[i] \text{ xor } x] + 1$ 即可。

```
typedef long long ll;
const int N=1e5+2,M=1<<14;
ll f[N],ans[N],ta[N];
int a[N],cnt[M],bel[N],pc[M],st[N];
int n,m,ksiz;
struct Q
{
    int z,y,wz;
    bool operator<(const Q& x) const {return (bel[z]<bel[x.z])||(bel[z]==bel[x.z])&&((y<x.y)&&(bel
        [z]&1)||(y>x.y)&&(1^bel[z]&1));}
};
Q mq(const int x,const int y,const int z)
{
    Q a;
    a.z=x;a.y=y;a.wz=z;
    return a;
}

        if (b[i][j].wz>0) ans[b[i][j].wz]+=na; else ans[-b[i][j].wz]-=na;
    }
}
for (i=2;i<=m;i++) ans[i]+=ans[i-1];
for (i=1;i<=m;i++) ta[q[i].wz]=ans[i];
for (i=1;i<=m;i++) printf("%lld\n",ta[i]);
```

```
}
```

2.13 回滚莫队

不删除的莫队，比如求 max。

做法：块内询问暴力。对于 l 所在块相同的询问，按照 r 升序排序，并且将左指针固定在 l 所在块的最右侧。(由于块内询问暴力，这不会导致左指针更大)

回答每个询问的时候，先右端点右移到 r，然后左端点左移到 l。询问完成后，把左端点移回去。移回去的过程虽然涉及删除，但不需要维护答案变成什么了(因为在左端点左移之前已经求过了)。换句话说，相当于"撤销"而不是删除，完全可以记录移动过程中的所有变化来撤销。

$O(n\sqrt{n})$，$O(n)$。

```
#include <bits/stdc++.h>
using namespace std;
const int N=2e5+2;
int a[N],z[N],y[N],wz[N],b[N],d[N],bel[N],ans[N],st[N][2],pos[N][2];
void qs(int l,int r)
{
    int i=l,j=r,m=bel[z[l+r>>1]],mm=y[l+r>>1];
    while (i<=j)
    {
        while ((bel[z[i]]<m)||(bel[z[i]]==m)&&(y[i]<mm)) ++i;
        while ((bel[z[j]]>m)||(bel[z[j]]==m)&&(y[j]>mm)) --j;
        if (i<=j)
        {
            swap(wz[i],wz[j]);
            swap(z[i],z[j]);
            swap(y[i++],y[j--]);
        }
    }
    if (i<r) qs(i,r);
    if (l<j) qs(l,j);
}
int main()
{
    read(n);ksiz=sqrt(n);

2.14 李超树

题意：插入线段，查询某个 x 的最大 y（输出最小编号）

算法核心：修改时，线段树每个点只维护在中点取值最大的线段，中点取值较小的线段只会在至多一侧有用，递归下去插入，复杂度 $O(\log^2)$。查询时询问线段树上 log 个点的线段中最大的。

```

2.23 Segmenttree Beats!

核心是 P（tag）和 Q（info）的维护。线段树部分是套的模板，并非全都有用。

1. l, r, k：对于所有的 $i \in [l, r]$，将 A_i 加上 k（k 可以为负数）。

2. l, r, v：对于所有的 $i \in [l, r]$，将 A_i 变成 $\min(A_i, v)$。

3. l, r：求 $\sum\limits_{i=l}^{r} A_i$。

4. l, r：对于所有的 $i \in [l, r]$，求 A_i 的最大值。

5. l, r：对于所有的 $i \in [l, r]$，求 B_i 的最大值。

其中 B_i 是 A_i 的历史最大值。

```
struct P
{
    ll tg,L,R;
    P(ll a=0,ll b=-inf,ll c=inf):tg(a),L(b),R(c) { }
    void operator+=(P o)

2.30 表达式树

传入表达式，输出表达式树。

输入的第二个参数是全体括号以外的运算符，每个运算符要记录字符优先级和是否右结合。优先级数字越大，越优先计算，且优先级必须为正整数。

输出的第一个参数是子结点数组，第二个参数是每个结点对应的字符，第三个参数是根。结点编号从 1 开始。

输出的表达式树满足每个结点对应一个字符。若包含数字串，则视为相邻数码之间加一个井号，表示“数码链接”这个运算符。你不需要，也不应该手动加入这个井号。

如果表达式非法，将返回根为 0。不允许一元运算符（负号），不允许省略乘号，不允许出现字母（除非字母是运算符）。

如果需要支持字母作为数字，修改所有包含 `isdigit` 的部分。

由于存在“数码链接”，在 dfs 树的时候最好记录一下子树大小，便于链接时计算（你不能在链接时直接看右子树的数字大小，因为有可能有前导 0）。

```
struct Q
{
    char ch;
    int prec;
    bool right;
};
tuple<vector<array<int, 2>>, vector<char>, int> parse_expr(string s, vector<Q> op) {
    static int idx[128];
    int maxp = 0, pos = 0, n, err = 0, i;
    {
        string t;
        for (char c : s)
        {
            if (t.size() && isdigit(t.back()) && isdigit(c)) t += '#';
            t += c;
        }
        swap(s, t);
        n = s.size();
    }
    for (i = 0; i < op.size(); ++i)
    {
        idx[op[i].ch] = i + 1;
        cmax(maxp, op[i].prec);
    }
    op.push_back({'#', ++maxp, 0});
    idx['#'] = op.size();
    vector<array<int, 2>> c(1);
    vector<char> ch(1);
    auto node = [&](char x) {
        c.push_back({0, 0});
        ch.push_back(x);
        return c.size() - 1;
    };
    function<int(int)> parse = [&](int lv) -> int {
        int u;
        if (lv > maxp)
        {
            if (pos < n && s[pos] == '(')
            {
                pos++;
                u = parse(1);
```

```
            if (err |= (pos >= n || s[pos++] != ')')) return 0;
            return u;
        }
        else if (pos < n && isdigit(s[pos])) return u = node(s[pos++]);
        else return err = 1, 0;
    }
    else
    {
        u = parse(lv + 1);
        while (!err && pos < n)
        {
            char ch = s[pos];
            int i = idx[ch] - 1;
            if (i >= 0 && op[i].prec == lv)

                ++pos;
                int v = node(ch), w = parse(lv + !op[i].right);
                c[v] = {u, w};
                u = v;
            }
            else break;
        }
        return u;
    }
};
int root = parse(0);
for (auto [ch, _, __] : op) idx[ch] = 0;
if (err || pos != n) return {{ }, { }, 0};
return {c, ch, root};
}
int main()
{
    ios::sync_with_stdio(0); cin.tie(0);
    cout << fixed << setprecision(15);
    string s;
    getline(cin, s);
    vector<Q> op = {
        {'|', 1, 0},
        {'&', 2, 0},
    };
    auto [c, ch, root] = parse_expr(s, op);
    assert(root);
    function<array<int, 3>(int)> dfs = [&](int u)->array<int, 3> {
        if (isdigit(ch[u])) return {ch[u] - '0', 0, 0};
        auto [l, r1, r2] = dfs(c[u][0]);
        if (ch[u] == '|')
        {
            if (l) return {1, r1, r2 + 1};
            auto [r, r3, r4] = dfs(c[u][1]);
            return {r, r1 + r3, r2 + r4};
        }
        else
        {
            if (!l) return {0, r1 + 1, r2};
            auto [r, r3, r4] = dfs(c[u][1]);
            return {r, r1 + r3, r2 + r4};
        }
```

```
    };
    auto [r0, r1, r2] = dfs(root);
    cout << r0 << endl << r1 << '␣' << r2 << endl;
}
```

3 数学

3.1 单情况矩阵 (+)

没啥用。特殊的 ddp 有用。

```
template<class T,int n> struct matrix
{
    #define all(x) (x).begin(),(x).end()
    array<pair<int,T>,n> a;
    matrix(char c='E')
    {
        int i;
        if (c=='E') for (i=0;i<n;i++) a[i]={i,0};
        else assert(0);
    }
    matrix(char c,int x)
    {

    }
    matrix operator+(const matrix &o) const
    {
        matrix r;
        int i,j,k;
        for (i=0;i<n;i++)
        {
            auto [x,y]=a[i];
            r.a[i]={o.a[x].first,o.a[x].second+y};
        }
        return r;
    }
};
```

3.2 矩阵求逆（要求质数）

一种原地算法，总体效率更高。

$O(n^3)$，$O(n)$。

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
const int N=402,p=1e9+7;
void inv(int &x)
{
    int y=p-2,r=1;
    while (y)
    {
        if (y&1) r=(ll)r*x%p;
        x=(ll)x*x%p;
        y>>=1;
    }
    x=r;
}
int a[N][N],ih[N],jh[N];
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
```

```
    int i,j,k,n;
    cin>>n;
    for (i=0;i<n;i++) for (j=0;j<n;j++) cin>>a[i][j];
    memset(ih,-1,sizeof ih);
    memset(jh,-1,sizeof jh);
    for (k=0;k<n;k++)
    {//ih,jh要清空
        for (i=k;i<n;i++) if (ih[k]==-1) for (j=k;j<n;j++) if (a[i][j])
        {
            ih[k]=i;
            jh[k]=j;
            break;
        }
        if (ih[k]==-1) return cout<<"No␣Solution"<<endl,0;
        for (j=0;j<n;j++) swap(a[k][j],a[ih[k]][j]);
        for (i=0;i<n;i++) swap(a[i][k],a[i][jh[k]]);
        if (!a[k][k]) return cout<<"No␣Solution"<<endl,0;inv(a[k][k]);
        for (i=0;i<n;i++) if (i!=k) a[k][i]=(ll)a[k][i]*a[k][k]%p;
        for (i=0;i<n;i++) if (i!=k) for (j=0;j<n;j++) if (j!=k) a[i][j]=(a[i][j]+(ll)(p-a[i][k])*a
             [k][j])%p;
        for (i=0;i<n;i++) if (i!=k) a[i][k]=(ll)(p-a[i][k])*a[k][k]%p;
    }
    for (k=n-1;k>=0;k--)
    {
        for (j=0;j<n;j++) swap(a[k][j],a[jh[k]][j]);
        for (i=0;i<n;i++) swap(a[i][k],a[i][ih[k]]);
    }
}
/*
输入
3
1 2 8
2 5 6
5 1 2
输出
718750005 718750005 968750007
171875001 671875005 296875002
117187501 867187506 429687503
*/
```

3.3 任意模数矩阵求逆（未验证）

$O(n^3)$，$O(n^2)$。

原理和任意模数行列式类似，辗转相除。注意仍然要求对角线元素是有逆的。

```
int ksm(int x,int y)
{
    int r=1;
    while (y)
    {
        if (y&1) r=(ll)r*x%p;
        y>>=1;x=(ll)x*x%p;
    }
    return r;
}
int phi(int n)
```

```
{
    int r=n;
    for (int i=2;i*i<=n;i++) if (n%i==0)
    {
        r=r/i*(i-1);n/=i;
        while (n%i==0) n/=i;
    }
    if (n>1) r=r/n*(n-1);
    return r;
}
void cal(int a[][N],int b[][N],int n)
{
    int i,j,k,r,ph=phi(p);
    for (i=1;i<=n;i++) memset(b+1,0,n<<2);
    for (i=1;i<=n;i++) b[i][i]=1;
    for (i=1;i<=n;i++)
    {
        k=i;
        for (j=i+1;j<=n;j++) if (a[j][i]&&a[j][i]<a[k][i]) k=j;
        if (!a[k][i]) {puts("No␣Solution");exit(0);}
        swap(a[i],a[k]);swap(b[i],b[k]);
        for (j=i+1;j<=n;j++) if (a[j][i])
        {
            r=p-a[j][i]/a[i][i];
            for (k=i;k<=n;k++) a[j][k]=(a[j][k]+(ll)r*a[i][k])%p;
            for (k=1;k<=n;k++) b[j][k]=(b[j][k]+(ll)r*b[i][k])%p;
            while (a[j][i])
            {
                swap(a[i],a[j]);swap(b[i],b[j]);
                r=p-a[j][i]/a[i][i];
                for (k=i;k<=n;k++) a[j][k]=(a[j][k]+(ll)r*a[i][k])%p;
                for (k=1;k<=n;k++) b[j][k]=(b[j][k]+(ll)r*b[i][k])%p;
            }
        }
        if (__gcd(a[i][i],p)!=1) {puts("No␣Solution");exit(0);}
        r=ksm(a[i][i],ph-1);
        for (j=i;j<=n;j++) a[i][j]=(ll)a[i][j]*r%p;
        for (j=1;j<=n;j++) b[i][j]=(ll)b[i][j]*r%p;
        assert(a[i][i]==1);
        for (j=1;j<i;j++)
        {
            r=p-a[j][i];
            for (k=i;k<=n;k++) a[j][k]=(a[j][k]+(ll)r*a[i][k])%p;
            for (k=1;k<=n;k++) b[j][k]=(b[j][k]+(ll)r*b[i][k])%p;
        }
    }
}
```

3.4 矩阵的特征多项式

$O(n^3)$，$O(n^2)$。

封装版本见矩阵类。

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
```

```
const int N=502,p=998244353;
int a[N][N],f[N];
int n,i,j,k,x,y,r;
void inc(int &x,const int y)
{
    if ((x+=y)>=p) x-=p;
}
void dec(int &x,const int y)
{
    if ((x-=y)<0) x+=p;
}
int ksm(int x,int y)
{
    int r=1;
    while (y)
    {
        if (y&1) r=(ll)r*x%p;
        x=(ll)x*x%p;y>>=1;
    }
    return r;
}
void calmatrix(int a[N][N],int n)
{
    int i,j,k,r;
    for (i=2;i<=n;i++)
    {
        for (j=i;j<=n&&!a[j][i-1];j++);
        if (j>n) continue;
        if (j>i)
        {
            swap(a[i],a[j]);
            for (k=1;k<=n;k++) swap(a[k][j],a[k][i]);
        }
        r=a[i][i-1];
        for (j=1;j<=n;j++) a[j][i]=(ll)a[j][i]*r%p;
        r=ksm(r,p-2);
        for (j=i-1;j<=n;j++) a[i][j]=(ll)a[i][j]*r%p;
        for (j=i+1;j<=n;j++)
        {
            r=a[j][i-1];
            for (k=1;k<=n;k++) a[k][i]=(a[k][i]+(ll)a[k][j]*r)%p;
            r=p-r;
            for (k=i-1;k<=n;k++) a[j][k]=(a[j][k]+(ll)a[i][k]*r)%p;
        }
    }
}
void calpoly(int a[N][N],int n,int *f)
{
    static int g[N][N];
    memset(g,0,sizeof(g));
    g[0][0]=1;
    int i,j,k,r,rr;
    for (i=1;i<=n;i++)
    {
        r=p-1;
        for (j=i;j;j--)//第 j 行选第 n 列
        {
```

```
        rr=(ll)r*a[j][i]%p;
        for (k=0;k<j;k++) g[i][k]=(g[i][k]+(ll)rr*g[j-1][k])%p;
        r=(ll)r*a[j][j-1]%p;
      }
      for (k=1;k<=i;k++) inc(g[i][k],g[i-1][k-1]);
    }
    memcpy(f,g[n],n+1<<2);
    //if (n&1) for (i=0;i<=n;i++) if (f[i]) f[i]=p-f[i];//若注释掉则为 |kE-A|
}
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    cin>>n;
    for (i=1;i<=n;i++) for (j=1;j<=n;j++) cin>>a[i][j];
    calmatrix(a,n);calpoly(a,n,f);
    for (i=0;i<=n;i++) cout<<f[i]<<"x^"<<i<<"+\n"[i==n];
}
/*
3
1 2 3
4 5 6
7 8 9
输出: 0x^0+998244335x^1+998244338x^2+1x^3
*/
```

3.5 矩阵类（较新）

```
typedef unsigned long long ll;
const ll p=998244353;
ll ksm(ll x, ll y)
{
    ll r=1;
    while (y)
    {
        if (y&1) r=r*x%p;
        x=x*x%p; y>>=1;
    }
    return r;
}
struct matrix:vector<vector<ll>>
{
    explicit matrix(int n=0, int m=0):vector(n, vector<ll>(m)) { }

3.6 最短递推式（BM 算法）

给定 $\{a\}$，求最短的 $\{r\}$ 满足 $\sum_{j=0}^{m-1} a_{i-j-1}r_j = a_i$。

```
vector<ui> bm(const vector<ui> &a)
{
    vector<ui> r,lst;
    int n=a.size(),m=0,q=0,i,j,k=-1;
    ui D=0;
    for (i=0;i<n;i++)
    {
        ui cur=0;
        for (j=0;j<m;j++) cur=(cur+(ll)a[i-j-1]*r[j])%p;
        cur=(a[i]+p-cur)%p;
        if (!cur) continue;
        if (k==-1)
        {
            k=i;
            D=cur;
            r.resize(m=i+1);
            continue;
```

```
        }
        auto v=r;
        ui x=(ll)cur*ksm(D,p-2)%p;
        if (m<q+i-k) r.resize(m=q+i-k);
        (r[i-k-1]+=x)%=p;
        ui *b=r.data()+i-k;
        x=(p-x)%p;
        for (j=0;j<q;j++) b[j]=(b[j]+(ll)x*lst[j])%p;
        if (v.size()+k<lst.size()+i)
        {
            lst=v;
            q=v.size();
            k=i;
            D=cur;
        }
    }
    return r;
}
```

3.7 在线 $O(1)$ 逆元

预处理复杂度为 $O(p^{\frac{2}{3}})$。

```
namespace online_inv
{
    typedef unsigned int ui;
    typedef unsigned long long ll;
    const ll p=1e9+7,n=1010,m=n*n,N=m+2;
    int l[N],r[N];
    ll y[N];
    bool s[N];
    ll _inv[N*2],i,j,k;
    void init_inv()
    {
        assert(n*n*n>p);
        _inv[1]=1;
        for (i=2;i<m*2;i++)
        {
            j=p/i;
            _inv[i]=(p-j)*_inv[p-i*j]%p;
        }
        s[0]=y[0]=1;
        for (i=1;i<n;i++) for (j=i;j<n;j++) if (!s[k=i*m/j])
        {
            y[k]=j;
            s[k]=1;
        }

```

3.9 扩展欧拉定理

求 $a \uparrow\uparrow b \bmod c$。前面的 Prime 命名空间只是求 φ 用的。

```
namespace Prime
{
    typedef unsigned int ui;
    typedef unsigned long long ll;
    const int N=1e6+2;
    const ll M=(ll)(N-1)*(N-1);
    ui pr[N],mn[N],phi[N],cnt;
    int mu[N];
    void init_prime()
    {
        ui i,j,k;
        phi[1]=mu[1]=1;
        for (i=2;i<N;i++)
        {
            if (!mn[i])
            {
                pr[cnt++]=i;
                phi[i]=i-1;mu[i]=-1;
                mn[i]=i;
            }
            for (j=0;(k=i*pr[j])<N;j++)
            {
                mn[k]=pr[j];
                if (i%pr[j]==0)
                {
                    phi[k]=phi[i]*pr[j];
                    break;
                }
                phi[k]=phi[i]*(pr[j]-1);
                mu[k]=-mu[i];
            }
        }
        //for (i=2;i<N;i++) if (mu[i]<0) mu[i]+=p;
    }
    template<class T> T getphi(T x)
    {
        assert(M>=x);
        T r=x;
        for (ui i=0;i<cnt&&(T)pr[i]*pr[i]<=x&&x>=N;i++) if (x%pr[i]==0)

        }
        if ((x*=x)>=p) x=x%p+p; else x%=p;
        y>>=1;
    }
    return r;
}
struct Q
{
    vector<ui> p;
    Q(const ui &P)
    {
        p.push_back(P);
        while (p.back()>1) p.push_back(getphi(p.back()));
    }
    ui operator()(ll a,ll b)
    {
        if (!a) return (1^b&1)%p[0];
        ui r=1;
        int i=min(b,(ll)p.size());
```

```
        while ((--i)>=0) r=ksm(a,r,p[i]);
        return r%p[0];
    }
};
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    cout<<setiosflags(ios::fixed)<<setprecision(15);
    int n,i;
    init_prime();
    int T;
    cin>>T;
    while (T--)
    {
        ui a,b,c;
        cin>>a>>b>>c;
        cout<<Q(c)(a,b)<<'\n';
    }
}
```

3.10 exgcd

$O(\log p)$，$O(\log p)$。

递归版：

```
int exgcd(int a,int b,int c)//ax+by=c,return x
{
    if (a==0) return c/b;
    return (c-(ll)b*exgcd(b%a,a,c))/a%b;
}
```

递推重构版：

```
pair<ll,ll> exgcd(ll a,ll b,ll c)//ax+by=c，{-1,-1} 无解，b=0 返回 {c/a,0}，否则返回最小非负 x
{
    assert(a||b);
    if (!b) return {c/a,0};
    if (a<0) a=-a,b=-b,c=-c;
    ll d=gcd(a,b);
    if (c%d) return {-1,-1};
    ll x=1,x1=0,p=a,q=b,k;
    b=abs(b);
    while (b)
    {
        k=a/b;
        x-=k*x1;a-=k*b;
        swap(x,x1);
        swap(a,b);
    }
    b=abs(q/d);
    x=(c/d)%b*(x%b)%b;
    if (x<0) x+=b;
    return {x, (ll)((c-(lll)p*x)/q)};
}
ll fun(ll a, ll b, ll p)//ax=b(mod p)
{
    return exgcd(a, -p, b).first%p;
```

```
}
```

3.11 exCRT

实现了一个类 Q，表示一条方程，支持合并。

```
namespace CRT
{
    typedef long long ll;
    pair<ll,ll> exgcd(ll a,ll b,ll c)
    {
        assert(a||b);
        if (!b) return {c/a,0};
        ll d=gcd(a,b);
        if (c%d) return {-1,-1};
        ll x=1,x1=0,p=a,q=b,k;
        b=abs(b);
        while (b)
        {
            k=a/b;
            x-=k*x1;a-=k*b;
            swap(x,x1);
            swap(a,b);
        }
        b=abs(q/d);
        x=x*(c/d)%b;
        if (x<0) x+=b;
        return {x,(c-p*x)/q};
    }
    struct Q
    {
        ll p,r;//0<=r<p
        Q operator+(const Q &o) const
        {
            if (p==0||o.p==0) return {0,0};
            auto [x,y]=exgcd(p,-o.p,r-o.r);
            if (x==-1&&y==-1) return {0,0};
            ll q=lcm(p,o.p);
            return {q,((r-x*p)%q+q)%q};

```

3.14 杜教筛

求 $\varphi(n)$ 的前缀和。

核心：构造 g 满足 $h(n)=\sum\limits_{d|n} f(d)g(\frac{n}{d})$ 容易计算，

则有 $\sum\limits_{i=1}^{n} h(i)=\sum\limits_{i=1}^{n} g(i)\sum\limits_{j=1}^{\lfloor n/i\rfloor} f(j)$，

故 $g(1)\sum\limits_{j=1}^{n} f(j)=\sum\limits_{i=1}^{n} h(i)-\sum\limits_{i=2}^{n} g(i)\sum\limits_{j=1}^{\lfloor n/i\rfloor} f(j)$，

则 f 前缀和可以递归求解。

```
namespace du_seive
{
    typedef unsigned int ui;
    typedef unsigned long long ll;
    unordered_map<ll,ui> mp;
    const int N=1e7+2;
    const ui p=998244353;
    ui pr[N],phi[N];
    ui cnt;
    void init()
    {
        cnt=0;phi[1]=1;
        int i,j;
        for (i=2;i<N;i++)
        {
            if (!phi[i])
            {
                pr[cnt++]=i;
                phi[i]=i-1;
            }
            for (j=0;i*pr[j]<N;j++)
            {
                if (i%pr[j]==0)
                {
                    phi[i*pr[j]]=phi[i]*pr[j];
                    break;
```

```
            }
            phi[i*pr[j]]=phi[i]*(pr[j]-1);
         }
         if ((phi[i]+=phi[i-1])>=p) phi[i]-=p;
      }
   }
   ui get_phi_sum(ll n)

{
    ll n;
    init();
    cin >> n;
    cout << sum_mu2(n) << endl;
}
```

3.16 线性规划

用法：构造函数指明目标函数系数，add 函数增加限制。额外的限制是 $x_i \geq 0$。

```
typedef long double db;//__float128
struct linear
{
    static const int N=45;//n+m
    db r[N][N];
    int col[N],row[N];
    const db eps=1e-10,inf=1e9;//1e-17
    int n,m;
    template<class T> linear(const vector<T> &a)//target: maximize \sum a(i-1)xi
    {
        memset(r,0,sizeof r);
        memset(col,0,sizeof col);
        memset(row,0,sizeof row);
        n=a.size();m=0;
        for (int i=1;i<=n;i++) r[0][i]=-a[i-1];
    }
    template<class T> void add(const vector<T> &a,db b)//limit: \sum a(i-1)xi<=b
    {
        assert(a.size()==n);
        ++m;
        for (int i=1;i<=n;i++) r[m][i]=-a[i-1];
        r[m][0]=b;
    }
    void pivot(int k, int t)
    {
        swap(row[k+n],row[t]);
        db rkt=-r[k][t];
        int i,j;
        for (i=0;i<=n;i++) r[k][i]/=rkt;
```

```
    r[k][t]=-1/rkt;
    for (i=0;i<=m;i++) if (i!=k)
    {
        db rit=r[i][t];
        if (rit>=-eps&&rit<=eps) continue;
        for (j=0;j<=n;j++) if (j!=t) r[i][j]+=rit*r[k][j];
        r[i][t]=r[k][t]*rit;
    }
}

```

3.30 模数为偶数 FWT & 光速乘

$O(n2^n)$，$O(2^n)$。

原理：让模数变为 $p2^n$，就可以正常做除法了。

```
const int N=1<<20,M=21;
int x[M];
ll p,f[N],g[N];
int n,m,c;
ll mul(ll x,ll y)
{
    x=x*y-(ll)((ldb)x/p*y+1e-8)*p;
    if (x<0) return x+p;return x;
}
void dft(ll *a)
{
    int i,j,k,l;
    ll b;
    for (i=1;i<n;i=l)
    {
        l=i<<1;
        for (j=0;j<n;j+=l) for (k=0;k<i;k++)
```

```
        {
            b=a[j|k|i];
            a[j|k|i]=(a[j|k]-b+p)%p;
            a[j|k]=(a[j|k]+b)%p;
        }
    }
}
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    ll t;int i;
    cin>>m>>t>>p;p*=(n=1<<m);
    for (i=0;i<n;i++) cin>>f[i];
    dft(f);
    for (i=0;i<=m;i++) cin>>x[i];
    for (i=1;i<n;i++) g[i]=g[i>>1]+(i&1);

}
```

3.34 NTT

一种较快的 NTT（尤其是对于卷积以外的用途），但不推荐在不熟悉的情况下直接使用。一般的卷积可以参照字符串部分通配符的字符串匹配，其余的用途可以参照其他板子。

如果确实需要卡常，建议先抄写需要的函数，并递归地找到需要补的内容。

注意事项：所有 `ll` 为无符号。始终保证数组大小为 2^n，不应当使用 `resize` 而应该使用取模来调整长度。三种卷积对应的运算符见注释。

需要特别小心其长度的变化，注意不要越界。如果修改模数，`dft` 和 `hf_dft` 处有一个参数也要修改。

常见函数如下（带 new 的基本上都是较快但较长的）：

卷积 `operator*`，循环卷积 `operator&`，差卷积 `operator^`，求逆 `operator~/`（包含一个较短版，被注释了），分治 `cdq`，对数 `ln`，指数 `exp,exp_cdq,exp_new`，开方 `sqrt,sqrt_new`，幂函数 `pow(Q,ll),pow(Q,string),pow2(Q,ll),pow(Q,ll,Q)`，整除与取模 `div,mod,div_mod`，线性递推 `recurrent,recurrent_new,recurrent_interval`，连乘 `prod,prod_new`，
多点求值 `evaluation,evaluation_new`，阶乘 `factorial`，快速插值 `interpolation`，复合（逆）`comp,comp_inv`，多项式平移 `shift`，区间点值平移 `shift`，Z 变换 `Z_transform`，贝尔数（$[n]$ 划分等价类方案数）`Bell`，斯特林数 `S1_row,S1_column,S2_row,S2_column,signed_S1_row`，伯努利数 `Bernoulli`，划分数 `Partition`，最大公因式 `gcd`，求根 `root`，模多项式意义的逆 `inverse`。

```
#include <optional>
```

```

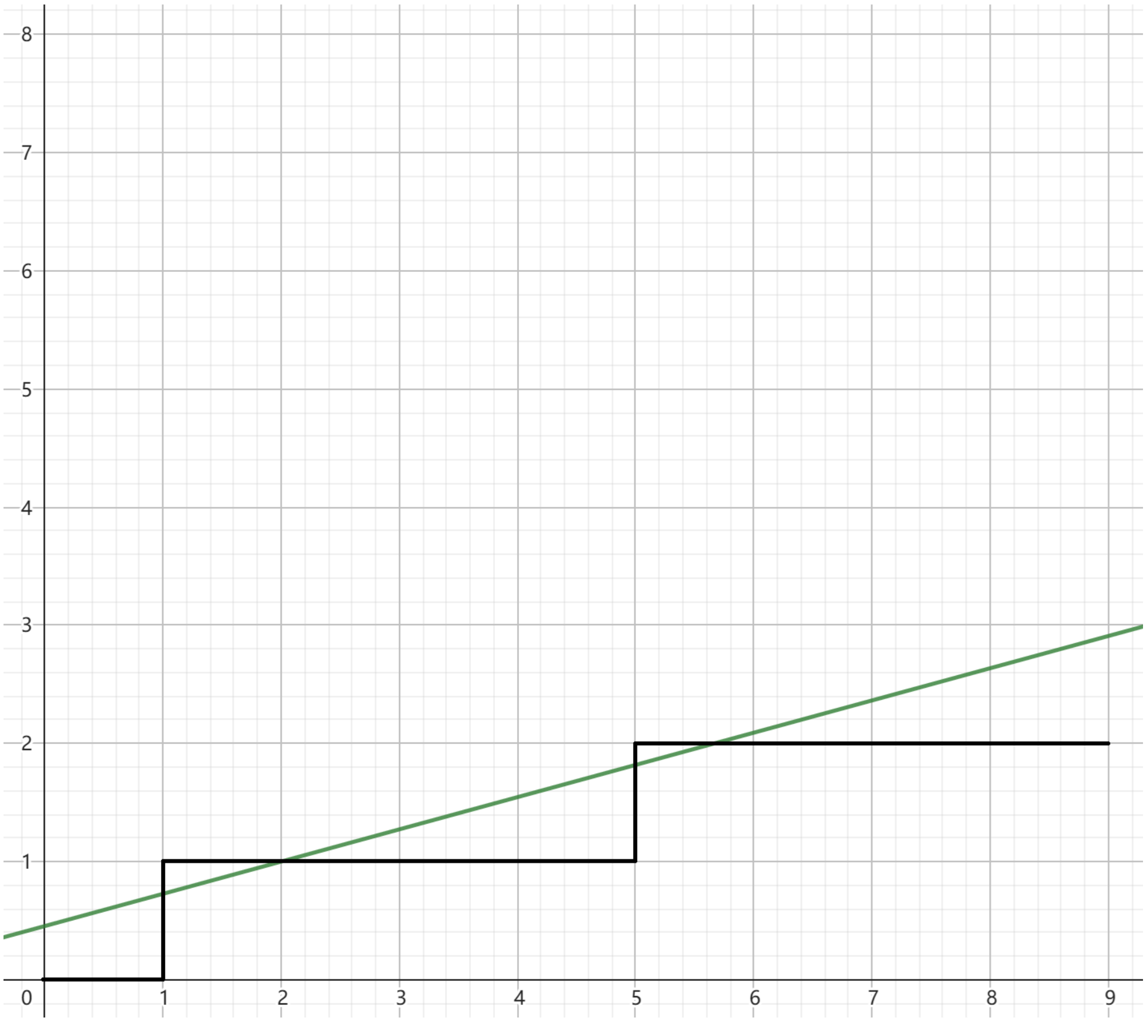
3.38 万能欧几里得/min of mod of linear

题意：$\sum_{x=0}^{n-1}\lfloor\frac{ax+b}{m}\rfloor$ （$0\le a,b<m$）



原理：考虑紧贴着斜线的折线的答案。每个 nd 表示的是一段折线，你需要实现 operator+ 来计算出拼接两个折线之后的答案。除此以外的原理不必了解。

你需要传入的 dx 和 dy 表示向上和向右的折线的答案（也就是边界）。

```
struct nd
{
    ll x, y, sy;
    nd operator+(const nd &o) const
    {
        return {x + o.x, y + o.y, sy + o.sy + y * o.x};
    }
};
nd ksm(nd a, int k)
{
```

```
    nd res{ };
    while (k)
    {
        if (k & 1) res = res + a;
        a = a + a; k >>= 1;
    }
    return res;
}
nd sol(int a, int b, int m, int n, nd dx, nd dy)//[0,n] (ax+b)/m 0<=b<m
{
    if (!n) return { };
    if (a >= m) return sol(a % m, b, m, n, ksm(dy, a / m) + dx, dy);

3.39 高斯整数类

圆上整点的基础。

```
ll roundiv(ll x,ll y)
{
    return x>=0?(x+y/2)/y:(x-y/2)/y;
}
struct Q
{
    ll x,y;
    Q operator~() const { return {x,-y}; }
    ll len2() const { return x*x+y*y; }
    Q operator+(const Q &o) const { return {x+o.x,y+o.y}; }
    Q operator-(const Q &o) const { return {x-o.x,y-o.y}; }
    Q operator*(const Q &o) const { return {x*o.x-y*o.y,x*o.y+y*o.x}; }
    Q operator/(const Q &o) const
    {
        Q t=*this*~o;
        ll l=o.len2();
```

```
        return {roundiv(t.x,l),roundiv(t.y,l)};
    }
    Q operator%(const Q &o) const { return *this-*this/o*o; }
};
Q gcd(Q a,Q b)
{
    if (a.len2()>b.len2()) swap(a,b);
    while (a.len2())
    {
        b=b%a;
        swap(a,b);
    }
    return b;
}
```

3.40 Miller Rabin/Pollard Rho

1s：200 组 10^{18}。

如果你只需要做 int 以内的分解，你可以改为

```
typedef int ll;
typedef long long lll;
```

```
namespace pr
{
    typedef long long ll;
    typedef __int128 lll;
    typedef pair<ll,int> pa;
    ll ksm(ll x,ll y,const ll p)
    {
        ll r=1;
        while (y)
        {
            if (y&1) r=(lll)r*x%p;
            x=(lll)x*x%p; y>>=1;
        }
        return r;
    }
    namespace miller
    {
        const int p[7]={2,3,5,7,11,61,24251};
        ll s,t;
        bool test(ll n,int p)
        {
            if (p>=n) return 1;
            ll r=ksm(p,t,n),w;
            for (int j=0; j<s&&r!=1; j++)
            {
                w=(lll)r*r%n;
                if (w==1&&r!=n-1) return 0;
                r=w;
            }
            return r==1;
        }
        bool prime(ll n)
        {
```

```
        if (n<2||n==46'856'248'255'981) return 0;
        for (int i=0; i<7; ++i) if (n%p[i]==0) return n==p[i];

using pr::getw,pr::getd,pr::prime;
```

4 字符串

4.1 字典树（trie 树）

```
struct trie
{
    const static int N=3e6+2, M=62;
    int c[N][M], sz[N];//sz 维护有多少个以当前字符串为前缀的字符串。
    int cnt;
    void insert(string s)
    {
        int u=0;
        ++sz[u];
        for (char ch:s)
        {
            assert(ch>=0&&ch<M);
            int &v=c[u][ch];
            if (!v) v=++cnt;
            u=v;
            ++sz[u];
        }
        //此时 u 是字符串结束位置。你可以在此存储结点信息。
    }
    int match(string s)//返回字符串结束位置。可能为 0。
    {
        int u=0;
        for (char ch:s)
        {
            assert(ch>=0&&ch<M);
            u=c[u][ch];
            if (!u) return 0;
        }
        return u;
    }
    void clear()
    {
        memset(c, 0, (cnt+1)*sizeof c[0]);
        memset(sz, 0, (cnt+1)*sizeof sz[0]);
        cnt=0;
    }
} s;
```

4.2 AC 自动机

注意 AC 自动机与 trie 不同的地方在于，根必须是 0。

题意：给你一个文本串 S 和 n 个模式串 $T_{1\sim n}$，请你分别求出每个模式串 T_i 在 S 中出现的次数。

```
struct AC
{
    const static int N=3e6+2, M=26;
    int c[N][M], sz[N], pos[N], f[N], app[N];//sz 维护有多少个以当前字符串为前缀的字符串。
    int cnt=0, id=0;
    vector<int> q;
    void insert(string s)
    {
```

```
        int u=0;
        ++sz[u];
        for (char ch:s)
        {
            assert(ch>=0&&ch<M);
            int &v=c[u][ch];
            if (!v) v=++cnt;
            u=v;
            ++sz[u];
        }
        pos[id++]=u;
        //此时 u 是字符串结束位置。你可以在此存储结点信息。
    }
    vector<int> match(string s)//返回答案。复杂度 O(结点数)
    {
        int u=0, i;
        for (char ch:s)
        {
            assert(ch>=0&&ch<M);
            u=c[u][ch];
            ++app[u];
        }
        for (int u:q) app[f[u]]+=app[u];
        vector<int> r(id);
        for (i=0; i<id; i++) r[i]=app[pos[i]];
        memset(app, 0, (cnt+1)*sizeof app[0]);
        return r;
    }
    void clear()
    {
        memset(c, 0, (cnt+1)*sizeof c[0]);
        memset(f, 0, (cnt+1)*sizeof f[0]);
        memset(sz, 0, (cnt+1)*sizeof sz[0]);
        cnt=id=0;
    }
    void build()
    {
        q.clear();
        int ql=0;
        for (int i=0; i<M; i++) if (c[0][i]) q.push_back(c[0][i]);
        while (ql<q.size())
        {
            int u=q[ql++];
            for (int i=0; i<M; i++) if (c[u][i])
            {
                q.push_back(c[u][i]);
                f[c[u][i]]=c[f[u]][i];
            }
            else c[u][i]=c[f[u]][i];
        }
        reverse(all(q));
    }
} s;
int main()
{
    ios::sync_with_stdio(0); cin.tie(0);
    int n, i;
```

```
    cin>>n;
    while (n--)
    {
        string t;
        cin>>t;
        for (char &c:t) c-='a';
        s.insert(t);
    }
    s.build();
    string t;
    cin>>t;
    for (char &c:t) c-='a';
    auto res=s.match(t);
    for (int x:res) cout<<x<<'\n';
}
```

4.3 hash

在调试时，可以把 base 设置为 10 的幂方便输出。可能建议把第一个模数也设置为 1，但未测试是否有奇怪的问题。但要注意，此时不应当使用接近 10 的幂次的模数。

$O(n)$，$O(n)$。

双模数版本：注意使用的是无符号数，效率比 int128 高，但不卡常建议抄 int128 版本。

特别注意这里 m 数组预处理的不是幂次，而是幂次的相反数。如果有复杂的变换需要建议用 int128 版本。

其返回值是两个 32 位数拼接而成的，要改动比较麻烦。

```
namespace sh
{
    typedef unsigned int ui;
    typedef unsigned long long ll;
    const int N=1e6+5;
    const ll p1=2'034'452'107, p2=2'013'074'419;
    struct pa
    {
        ll v1, v2;
        pa(ll v=0):v1(v), v2(v) { }
        pa(ll v1, ll v2):v1(v1), v2(v2) { }
        pa operator*(const pa &o) const { return {v1*o.v1%p1, v2*o.v2%p2}; }
    };
    pa fma(const pa &a, const pa &b, const pa &c) { return {(a.v1*b.v1+c.v1)%p1, (a.v2*b.v2+c.v2)%
        p2}; }
    const pa b={137, 149}, inv={1'603'801'661, 1'024'053'074};
    pa m[N];
    void init()
    {
        m[0]={p1-1, p2-1};
        for (int i=1; i<N; i++) m[i]=m[i-1]*b;
    }
    int i=(init(), 0);
    struct str
    {
        int n;
        vector<pa> a;
        template<class T> str(const vector<T> &s):n(s.size()), a(n+1)
        {
```

```
        for (i=0; i<n; i++) a[i+1]=fma(a[i], b, s[i]);
    }
    template<class T> str(const basic_string<T> &s):n(s.size()), a(n+1)//直接去掉模板换成
        string 也可以
    {
        for (i=0; i<n; i++) a[i+1]=fma(a[i], b, s[i]);
    }
    ll getv(int l, int r)//[l,r)
    {
        auto [x, y]=fma(a[l], m[r-l], a[r]);
        return x<<32|y;
    }
  };
}
using sh::str;
int main()
{
  ios::sync_with_stdio(0); cin.tie(0);
  int T; cin>>T;
  set<ull> s;
  while (T--)
  {
    string t;
    cin>>t;
    s.insert(str(t).getv(0, t.size()));
  }
  cout<<s.size()<<endl;
}
```

__int128 版本:

```
namespace sh
{
  typedef __uint128_t lll;
  const int N=1e6+5;
  const lll p=1'80'143'985'094'819'841, b=137;
  lll m[N];
  void init()
  {
    m[0]=1;
    for (int i=1; i<N; i++) m[i]=m[i-1]*b%p;
  }
  int i=(init(), 0);
  struct str
  {
    int n;
    vector<lll> a;
    template<class T> str(const vector<T> &s):n(s.size()), a(n+1)
    {
        for (i=0; i<n; i++) a[i+1]=(a[i]*b+s[i])%p;
    }
    template<class T> str(const basic_string<T> &s):n(s.size()), a(n+1)//直接去掉模板换成
        string 也可以
    {
        for (i=0; i<n; i++) a[i+1]=(a[i]*b+s[i])%p;
    }
    lll getv(int l, int r)//[l,r)
    {
```

```
        return (a[r]+(p-a[l])*m[r-l])%p;
      }
   };
}
using sh::str;
```

4.4 KMP

$O(n)$，$O(n)$。

```
struct str
{
   vector<int> nxt,s;
   int n;
   str(int *S,int _n)//[1,n]
   {
      n=_n;
      nxt.resize(n+1);
      s=vector<int>(S,S+n+1);
      int i,j=0;
      nxt[1]=0;
      for (i=2;i<=n;i++)
      {
         while (j&&s[i]!=s[j+1]) j=nxt[j];
         nxt[i]=j+=s[i]==s[j+1];
      }
   }
   vector<int> match(int *t,int m)//find s(str) in t (start pos)
   {
      vector<int> r;
      int i,j=0;
      for (i=1;i<=m;i++)
      {
         while (j&&t[i]!=s[j+1]) j=nxt[j];
         if ((j+=t[i]==s[j+1])==n) j=nxt[j],r.push_back(i-n+1);
      }
      return r;
   }
};
int main()
{
   ios::sync_with_stdio(0);cin.tie(0);
   string s,t;
   cin>>s>>t;
   int n=s.size(),m=t.size(),i;
   vector<int> a(n+1),b(m+1);
   for (i=1;i<=n;i++) a[i]=s[i-1];
   for (i=1;i<=m;i++) b[i]=t[i-1];
   str q(b.data(),m);
   auto r=q.match(a.data(),n);
   for (int x:r) cout<<x<<'\n';
   for (i=1;i<=m;i++) cout<<q.nxt[i]<<" \n"[i==m];
}
```

4.5 KMP（重构，未验证）

$O(n)$，$O(n)$。

```
struct str//[0,n)
{
	vector<int> nxt,s;
	int n;
	str(const vector<int> &_s):nxt(_s.size(),-1),s(all(_s)),n(_s.size())
	{
		int i,j=-1;
		for (i=1;i<n;i++)
		{
			while (j!=-1&&s[i]!=s[j+1]) j=nxt[j];
			nxt[i]=j+=s[i]==s[j+1];
		}
	}
	vector<int> match(const vector<int> &t)//find s(str) in t (start pos)
	{
		int m=t.size();
		vector<int> r;
		int i,j=-1;
		for (i=0;i<m;i++)
		{
			while (j!=-1&&t[i]!=s[j+1]) j=nxt[j];
			if ((j+=t[i]==s[j+1])==n-1) j=nxt[j],r.push_back(i-n+1);
		}
		return r;
	}
};
```

4.6 manacher

$O(n)$，$O(n)$。

```
vector<int> manacher(const string &t)//ex[i](total length) centered at i/2
{
	string S="$#";
	int n=t.size(),i,r=1,m=0;
	for (i=0;i<n;i++) S+=t[i],S+='#';
	S+='#';
	char *s=S.data()+2;
	n=n*2-1;
	vector<int> ex(n);
	ex[0]=2;
	for (i=1;i<n;i++)
	{
		ex[i]=i<r?min(ex[m*2-i],r-i+1):1;
		while (s[i+ex[i]]==s[i-ex[i]]) ++ex[i];
		if (i+ex[i]-1>r) r=i+ex[m=i]-1;
	}
	for (i=0;i<n;i++) --ex[i];
	return ex;
}
```

4.7 SA

$O((n+\sum)\log n)$，$O(n+\sum)$。
功能：查询两个后缀的 lcp。单次询问复杂度 $O(1)$。
下标从 1 开始。

```
struct SA
{
    int n;
    vector<vector<int>> st;
    vector<int> sa, rk, h;
    int lcp(int x, int y)
    {
        if (x == y) return n - x;
        x = rk[x]; y = rk[y];
        if (x > y) swap(x, y);
        ++x;
        int z = __lg(y - x + 1);
        return min(st[z][x], st[z][y - (1 << z) + 1]);
    }
    SA(vector<int> a) :n(a.size()), st(__lg(n) + 1, vector<int>(n + 1)), sa(n), h(n)
    {
        const static int N = 2e6 + 2;
        static int s[N];
        int i, j, m, cnt;
        m = *min_element(all(a));
        for (int &x : a) x -= m;
        m = *max_element(all(a)) + 1;
        assert(max(n, m) < N);
        a.resize(n * 2);
        for (i = 0; i < n; i++) a[i + n] = -i - 1;
        vector<int> id(n * 2);
        rk = a;
        for (i = 0; i < n; i++) ++s[a[i]];
        for (i = 1; i < m; i++) s[i] += s[i - 1];
        for (i = n - 1; i >= 0; i--) sa[--s[rk[i]]] = i;
        memset(s, 0, m * sizeof s[0]);
        for (j = 1; j <= n; j <<= 1)
        {
            cnt = 0;
            for (i = n - j; i < n; i++) id[cnt++] = i;
            for (i = 0; i < n; i++) if (sa[i] >= j) id[cnt++] = sa[i] - j;
            for (i = 0; i < n; i++) ++s[rk[i]];
            for (i = 1; i < m; i++) s[i] += s[i - 1];
            for (i = n - 1; i >= 0; i--) sa[--s[rk[id[i]]]] = id[i];
            id[sa[0]] = cnt = 0;
            memset(s, 0, m * sizeof s[0]);
            for (i = 1; i < n; i++)

};
```

4.12 Z 函数

表示每个后缀和母串的 lcp。

```
vector<int> Z(const string &s)
{
    int n=s.size(),i,l,r;
    vector<int> z(n);
    z[0]=n;
    for (i=1,l=r=0; i<n; i++)
    {
        if (i<=r&&z[i-l]<r-i+1) z[i]=z[i-l];
        else
        {
            z[i]=max(0,r-i+1);
            while (i+z[i]<n&&s[i+z[i]]==s[z[i]]) ++z[i];
        }
        if (i+z[i]-1>r) l=i,r=i+z[i]-1;
    }
    return z;
}
```

4.13 最小表示法

找到一个串的循环同构串中字典序最小的那个，将这个串直接变过去。常见应用：环哈希（基环树哈希）。

如果只需要找到起点下标，在 rotate 前返回 $\min\{i,j\}$ 即可。

$O(n)$，$O(1)$。

```
template<class T> void min_order(vector<T>& a)
{
    int n = a.size(), i, j, k;
    a.resize(n * 2);
    for (i = 0;i < n;i++) a[i + n] = a[i];
    i = k = 0;j = 1;
    while (i < n && j < n && k < n)
    {
        T x = a[i + k], y = a[j + k];
        if (x == y) ++k; else
        {
            (x > y ? i : j) += k + 1;
            j += (i == j);
            k = 0;
        }
    }
    a.resize(n);
    //[min(i,j),n)+[0,min(i,j))
    rotate(a.begin(), min(i, j) + all(a));
}
```

4.14 带通配符的字符串匹配

原理：匹配等价于 $\sum(f_i-g_i)^2=0$。带通配符等价于 $\sum f_ig_i(f_i-g_i)^2=0$，展开即可。

这里也是较为推荐的 NTT 版本，直接实现任意长度的多项式相乘，便于一般情况的运用。不需要提前做任何 init。

```
namespace NTT
{
    typedef unsigned ui;
    typedef unsigned long long ll;
    const int N=1<<22;
    const ui p=998244353, g=3;
    inline ui ksm(ui x, ui y)
    {
        ui ans=1;
        while (y)
        {
            if (y&1) ans=1llu*ans*x%p;
            y>>=1; x=1llu*x*x%p;
        }
        return ans;
    }
    ui r[N], w[N];
    void ntt(vector<ui> &a)
    {
        int n=a.size(), i, j, k;
        for (i=0; i<n; i++) if (i<r[i]) swap(a[i], a[r[i]]);
        for (k=1; k<n; k<<=1)
        {
            for (i=0; i<n; i+=k<<1)
            {
                for (j=0; j<k; j++)
                {
                    ui x=a[i+j], y=1llu*a[i+j+k]*w[j+k]%p;
                    a[i+j]=(x+y)%p; a[i+j+k]=(x+p-y)%p;
                }
            }
        }
    }
    vector<ui> mul(vector <ui> a, vector <ui> b)
    {
        if (a.size()==0||b.size()==0) return { };
        int m=a.size()+b.size()-1;
        int n=1<<__lg(m*2-1);
        int i, j, base=__lg(n)-1;
        ui inv=ksm(n, p-2);
        for (i=1; i<n; i++) r[i]=r[i>>1]>>1|(i&1)<<base;
        for (j=1; j<n; j<<=1)
        {
            ui wn=ksm(3, (p-1)/(j<<1));
            w[j]=1;
            for (i=1; i<j; i++) w[j+i]=1llu*w[j+i-1]*wn%p;
        }
        a.resize(n); b.resize(n);
        ntt(a); ntt(b);
        for (i=0; i<n; i++) a[i]=1llu*a[i]*b[i]%p;
        ntt(a); reverse(1+all(a)); a.resize(n=m);
        for (i=0; i<n; i++) a[i]=1llu*a[i]*inv%p;
        return a;
    }
}
vector<int> match(const string &s, const string &t)
```

```
{
    using NTT::p, NTT::mul;
    static mt19937 rnd(chrono::steady_clock::now().time_since_epoch().count());
    static array<ui, 256> c;
    static bool inited=0;
    if (!inited)
    {
        inited=1;
        for (ui &x:c) x=rnd()%NTT::p;
        c['*']=0;//通配符
    }
    int n=s.size(), m=t.size(), i, j;
    if (n<m) return { };
    vector<int> ans;
    vector<ui> f(n), ff(n), fff(n), g(m), gg(m), ggg(m);
    for (i=0; i<n; i++)
    {
        f[i]=c[s[i]];
        ff[i]=1llu*f[i]*f[i]%p;
        fff[i]=1llu*ff[i]*f[i]%p;
    }
    for (i=0; i<m; i++)
    {
        g[i]=c[t[m-i-1]];
        gg[i]=1llu*g[i]*g[i]%p;
        ggg[i]=1llu*gg[i]*g[i]%p;
    }
    auto fffg=mul(fff, g), ffgg=mul(ff, gg), fggg=mul(f, ggg);
    for (i=0; i<=n-m; i++) if ((fffg[m-1+i]+fggg[m-1+i]+2*(NTT::p-ffgg[m-1+i]))%NTT::p==0) ans.
        push_back(i);
    return ans;
}
```

快一些的版本，手动拆开了多项式乘法。

```
const int N=1<<22;
const ui p=998244353, g=3;
inline ui ksm(ui x, ui y)
{
    ui ans=1;
    while (y)
    {
        if (y&1) ans=1llu*ans*x%p;
        y>>=1; x=1llu*x*x%p;
    }
    return ans;
}
ui r[N], w[N];
void ntt(vector <ui> &a)

    return ans;
}
```

5 图论

5.1 最小密度环

求所有环中边权和除以边数最少的，$O(nm)$。更常用的做法是二分 spfa。

```
#include <bits/stdc++.h>
using namespace std;
const int N=3e3+5,M=1e4+5;
const double inf=1e18;
int u[M],v[M];
double f[N][N],w[M];
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    cout<<setiosflags(ios::fixed)<<setprecision(8);
    int n,m,i,j;
    cin>>n>>m;
    for (i=1;i<=m;i++) cin>>u[i]>>v[i]>>w[i];
    ++n;
    for (i=1;i<=n;i++)
    {
        fill_n(f[i]+1,n,inf);
        for (j=1;j<=m;j++) f[i][v[j]]=min(f[i][v[j]],f[i-1][u[j]]+w[j]);
    }
    double ans=inf;
    for (i=1;i<n;i++) if (f[n][i]!=inf)
    {
        double r=-inf;
        for (j=1;j<n;j++) r=max(r,(f[n][i]-f[j][i])/(n-j));
        ans=min(ans,r);
    }
    cout<<ans<<endl;
}
```

5.2 全源最短路与判负环

使用 floyd 实现全源最短路与判负环。注意边权较大时可能需要考虑 int128.

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
typedef pair<int,int> pa;
typedef tuple<int,int,int> tp;
const int N=152;
const ll inf=5e8;
ll dis[N][N],d[N][N];
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    while (1)
    {
        int n,m,q,i,j,k;
        cin>>n>>m>>q;
        if (tp(n,m,q)==tp(0,0,0)) return 0;
        for (i=0;i<n;i++) fill_n(dis[i],n,inf*inf);
        for (i=0;i<n;i++) dis[i][i]=0;
```

```
        while (m--)
        {
            int u,v,w;
            cin>>u>>v>>w;
            dis[u][v]=min(dis[u][v],(ll)w);
        }
        for (k=0;k<n;k++) for (i=0;i<n;i++) for (j=0;j<n;j++) dis[i][j]=max(min(dis[i][j],dis[i][k
            ]+dis[k][j]),-inf*2);
        for (i=0;i<n;i++) copy_n(dis[i],n,d[i]);
        for (k=0;k<n;k++) for (i=0;i<n;i++) for (j=0;j<n;j++) dis[i][j]=max(min(dis[i][j],dis[i][k
            ]+dis[k][j]),-inf*2);
        while (q--)
        {
            int u,v;
            cin>>u>>v;
            if (d[u][v]>inf) cout<<"Impossible\n"; else if (dis[u][v]!=d[u][v]||d[u][v]<-inf) cout
                <<"-Infinity\n"; else cout<<d[u][v]<<'\n';
        }
        cout<<'\n';
    }
}
```

5.3 三/四元环计数

不能处理有重边和自环的情况。

$O(m\sqrt{m})$，$O(n+m)$。

注意四元环数的是边四元环。点四元环需要去掉四点完全图个数 *2，似乎不太能做？

三元环是可以枚举的，你可以在 ans 改变处记录三元环 (i,u,v)。

```
ll triple(const vector<pair<int,int>> &edges)//start from 0
{
    int n=0,i;
    for (auto [u,v]:edges) n=max({n,u,v});
    ++n;
    vector<int> d(n),id(n),rk(n),cnt(n);
    vector<vector<int>> e(n);
    for (auto [u,v]:edges) ++d[u],++d[v];
    iota(all(id),0); sort(all(id),[&](int x,int y) { return d[x]<d[y]; });
    for (i=0; i<n; i++) rk[id[i]]=i;
    for (auto [u,v]:edges)
    {
        if (rk[u]>rk[v]) swap(u,v);
        e[u].push_back(v);
    }
    ll ans=0;
    for (i=0; i<n; i++)
    {
        for (int u:e[i]) cnt[u]=1;
        for (int u:e[i]) for (int v:e[u]) ans+=cnt[v];
        for (int u:e[i]) cnt[u]=0;
    }
    return ans;
}
ll quadruple(const vector<pair<int,int>> &edges)
{
    int n=0,i;
```

```
    for (auto [u,v]:edges) n=max({n,u,v});
    ++n;
    vector<int> d(n),id(n),rk(n),cnt(n);
    vector<vector<int>> e(n),lk(n);
    for (auto [u,v]:edges) ++d[u],++d[v];
    iota(all(id),0); sort(all(id),[&](int x,int y) { return d[x]<d[y]; });
    for (i=0; i<n; i++) rk[id[i]]=i;
    for (auto [u,v]:edges)
    {
        if (rk[u]>rk[v]) swap(u,v);
        e[u].push_back(v);
        lk[u].push_back(v);
        lk[v].push_back(u);
    }
    ll ans=0;
    for (i=0; i<n; i++)
    {
        for (int u:lk[i]) for (int v:e[u]) if (rk[v]>rk[i]) ans+=cnt[v]++;
        for (int u:lk[i]) for (int v:e[u]) cnt[v]=0;
    }
    return ans;
}
map<pair<int, int>, ll> quadruple(vector<pair<int, int>> edges)
{
    int n = 0, i;
    for (auto [u, v] : edges) n = max({n, u, v});
    ++n;
    map<pair<int, int>, int> ec;
    for (auto [u, v] : edges)
    {
        if (u > v) swap(u, v);
        ++ec[{u, v}];
    }
    vector<ll> c;
    edges.clear();
    for (auto [_, cc] : ec) edges.push_back(_), c.push_back(cc);
    vector d(n, 0), id(d), rk(d);
    vector<ll> cnt(n);
    vector<vector<pair<int, int>>> e(n), lk(n);
    for (auto [u, v] : edges) ++d[u], ++d[v];
    iota(all(id), 0); sort(all(id), [&](int x, int y) { return d[x] < d[y]; });
    for (i = 0; i < n; i++) rk[id[i]] = i;
    i = 0;
    for (auto [u, v] : edges)
    {
        if (rk[u] > rk[v]) swap(u, v);
        e[u].push_back({v, i});
        lk[u].push_back({v, i});
        lk[v].push_back({u, i});
        ++i;
    }
    int m = edges.size();
    vector<ll> ans(m);
    for (i = 0; i < n; i++)
    {
        for (auto [u, w1] : lk[i]) for (auto [v, w2] : e[u]) if (rk[v] > rk[i])
        {
```

```
            cnt[v] += c[w1] * c[w2];
        }
        for (auto [u, w1] : lk[i]) for (auto [v, w2] : e[u]) if (rk[v] > rk[i])
        {
            ans[w1] += (cnt[v] - c[w1] * c[w2]) * c[w2];
            ans[w2] += (cnt[v] - c[w1] * c[w2]) * c[w1];
        }
        for (auto [u, w1] : lk[i]) for (auto [v, w2] : e[u]) if (rk[v] > rk[i]) cnt[v] = 0;
    }
    map<pair<int, int>, ll> mp;
    for (i = 0;i < m;i++) mp[edges[i]] = ans[i];
    return mp;
}
int main()
{
    ios::sync_with_stdio(0); cin.tie(0);
    cout << fixed << setprecision(15);
    int n, m, i;
    cin >> n >> m;
    vector<pair<int, int>> eg(m);
    cin >> eg;
    auto mp = quadruple(eg);
    for (i = 0;i < m;i++)
    {
        auto [u, v] = eg[i];
        if (u > v) swap(u, v);
        cout << mp[{u, v}] << " \n"[i + 1 == m];
    }
}
```

5.4 最短路系列

Johnson 不适用于图中存在负环的情况，因为负环不一定是可以经过的。

$O(nm\log m)$，$O(n+m)$。

```
vector<ll> spfa(const vector<vector<pair<int, ll>>> &e, int s)
{
    int n=e.size(), i;
    assert(n);
    queue<int> q;
    vector<int> len(n), ed(n);
    vector<ll> dis(n, inf);
    q.push(s); dis[s]=0;
    while (q.size())
    {
        int u=q.front(); q.pop();
        ed[u]=0;
        for (auto [v, w]:e[u]) if (cmin(dis[v], dis[u]+w))
        {
            len[v]=len[u]+1;
            if (len[v]>n) return { };
            if (!ed[v])
            {
                ed[v]=1;
                q.push(v);
            }
```

```
      }
   }
   return dis;
}
vector<ll> spfa(const vector<vector<pair<int, ll>>> &e)
{
   int n=e.size(), i;
   assert(n);
   queue<int> q;
   vector<int> len(n), ed(n, 1);
   vector<ll> dis(n);
   for (i=0; i<n; i++) q.push(i);
   while (q.size())
   {
      int u=q.front(); q.pop();
      ed[u]=0;
      for (auto [v, w]:e[u]) if (cmin(dis[v], dis[u]+w))
      {
         len[v]=len[u]+1;
         if (len[v]>n) return { };
         if (!ed[v])
         {
            ed[v]=1;
            q.push(v);
         }
      }
   }
   return dis;
}
vector<ll> dijk(const vector<vector<pair<int, ll>>> &e, int s)
{
   int n=e.size();
   using pa=pair<ll, int>;
   vector<ll> d(n, inf);
   vector<int> ed(n);
   priority_queue<pa, vector<pa>, greater<pa>> q;
   d[s]=0; q.push({0, s});
   while (q.size())

   for (int i=0; i<e.size(); i++) r.push_back(dijk(e, i));
   return r;
}
vector<vector<ll>> john(vector<vector<pair<int, ll>>> e)
{
   int n=e.size(), i, j;
   assert(n);
   auto h=spfa(e);
```

```
    if (!h.size()) return { };
    for (i=0; i<n; i++) for (auto &[v, w]:e[i]) w+=h[i]-h[v];
    auto r=dijk(e);
    for (i=0; i<n; i++) for (j=0; j<n; j++) if (r[i][j]!=inf) r[i][j]-=h[i]-h[j];
    return r;
}
```

5.5 弦图

单纯点：v 和 v 邻点构成团。

完美消除序列：v_i 在 $\{v_i, v_{i+1}, \cdots, v_n\}$ 为单纯点。

$N(v_i) = \{v_j | j > i \wedge (v_i, v_j) \in E\}$，$next(v_i)$ 为 $N(v_i)$ 最靠前的点。

极大团一定是 $\{v\} \cup N(v)$ 。

最大团大小等于色数。

弦图判定：等价于是否存在完美消除序列。首先求出一个完美消除序列，然后判定是否合法。

判定方法：设 $v_{i+1}, \cdots, v_n$ 中与 v_i 相邻的依次为 $v'_1, \cdots, v'_m$。只需判断是否 v'_1 与 $v'_2, \cdots, v'_m$ 相邻。

LexBFS 算法（我不会写）

每个点有一个字符串 label，初始为 0。从 $i = n$ 到 $i = 1$ 确定，选 label 字典序最大的 u，再把 u 邻点的 label 后面接一个 i。

最大势算法：从 v_n 求到 v_1，设 $label_i$ 表示 i 与多少个已选点相邻，每次选 $label_i$ 最大的点。

弦图极大团：$\{v | \forall next(w) = v, |N(v)| \geq |N(w)|\}$。选出的集合为基本点，按上述极大团构造。

弦图染色：从 v_n 到 v_1 依次选最小可染的色。

最大独立集：从 v_1 到 v_n 能选就选。

最小团覆盖：设最大独立集为 $\{p_m\}$，最小团覆盖为 $\{\{p_i\} \cup N(p_i)\}$。

区间图：两个区间有边当且仅当交集非空。

区间图是弦图。

5.5.1 代码

```
namespace chordal_graph//下标从 1 开始
{
    const int N=1e5+2;//点数
    bool ed[N];

```

5.7 二分图与网络流建图

以下约定，若为二分图则 n, m 表示两侧点数，否则仅 n 表示全图点数。

5.7.1 二分图边染色

留坑待填。

结论：$\Delta(G) \le \chi'(G) \le \Delta(G)+1$，二分图时 $\chi'(G)=\Delta(G)$。$\Delta(G)$ 为图的最大度。

5.7.2 二分图最小点集覆盖

$ans = \text{maxmatch}$，方案如下。

```
#include <bits/stdc++.h>
using namespace std;
const int N=5e3+2;
vector<int> e[N];
int ed[N],lk[N],kl[N],flg[N],now;
bool dfs(int u)
{
    for (int v:e[u]) if (ed[v]!=now)
    {
        ed[v]=now;
        if (!lk[v]||dfs(lk[v])) return lk[v]=u;
    }
    return 0;
}
void dfs2(int u)
{
    for (int v:e[u]) if (!flg[v]) flg[v]=1,dfs2(lk[v]);
}
int main()
{
    int n,m,i,r=0;
    cin>>n>>m;
    while (m--)
    {
        int u,v;
        cin>>u>>v;
        e[u].push_back(v);
    }
    for (i=1;i<=n;i++) dfs(now=i);
    for (i=1;i<=n;i++) kl[lk[i]]=i;
    for (i=1;i<=n;i++) if (!kl[i]) dfs2(i);
    vector<int> A[2];
    for (i=1;i<=n;i++) if (lk[i])
    {
        if (flg[i]) A[1].push_back(i); else A[0].push_back(lk[i]);
    }
    for (int j=0;j<2;j++)
    {
        cout<<A[j].size();
        for (int x:A[j]) cout<<' '<<x;cout<<'\n';
    }
}
```

5.7.3 二分图最大独立集

$ans = n + m - \text{maxmatch}$，方案是最小点集覆盖的补集。

5.7.4 二分图最小边覆盖

$ans = n + m - \text{maxmatch}$，方案是最大匹配加随便一些边（用于覆盖失配点）。无解当且仅当有孤立点，算法会视为单选孤立点（无边）。这个定理对一般图也成立。

5.7.5 有向无环图最小不相交链覆盖

$ans = n - \mathrm{maxmatch}$，其中二分图建图方法是拆入点和出点（实现时直接跑一次二分图就行，不用额外处理），注意**不**需要传递闭包。方案如下。

```
#include <bits/stdc++.h>
using namespace std;
const int N=152;
vector<int> e[N];
int lk[N],kl[N],ed[N],now;
bool dfs(int u)
{
    for (int v:e[u]) if (ed[v]!=now)
    {
        ed[v]=now;
        if (!lk[v]||dfs(lk[v])) return lk[v]=u;
    }
    return 0;
}
int main()
{
    int n,m,i;
    ios::sync_with_stdio(0);cin.tie(0);
    cin>>n>>m;
    while (m--)
    {
        int u,v;
        cin>>u>>v;
        e[u].push_back(v);
    }
    int r=0;
    for (i=1;i<=n;i++) r+=dfs(now=i);
    for (i=1;i<=n;i++) kl[lk[i]]=i;
    for (i=1;i<=n;i++) if (ed[i]!=-1&&!lk[i])
    {
        vector<int> ans;
        int u=i;
        while (u)
        {
            ed[u]=-1;
            ans.push_back(u);
            u=kl[u];
        }
        for (int j=0;j<ans.size();j++) cout<<ans[j]<<" \n"[j+1==ans.size()];
    }
    cout<<n-r<<endl;
}
```

5.7.6 有向无环图最大互不可达集

$ans = n - \mathrm{maxmatch}$，其中二分图建图方法是拆入点和出点（实现时直接跑一次二分图就行，不用额外处理），注意**需要**传递闭包。方案？

5.7.7 最大权闭合子图

若 $v_i>0$，$s\to i$ 流量 v_i；若 $v_i<0$，$i\to t$ 流量 $-v_i$。若原图 $u\to v$ 可花费 w 代价违抗，流量 w，否则 $+\infty$ 。答案为 $\sum\limits_{v_i>0} v_i-\text{maxflow}$。方案？

5.8 二分图匹配（时间戳写法）

```
bool dfs(int u)
{
    for (int v:e[u]) if (ed[v]!=now)
    {
        ed[v]=now;
        if (!lk[v]||dfs(lk[v])) return lk[v]=u;
    }
    return 0;
}
```

5.9 二分图最大权匹配

```

    for (auto [u,v,w]:e) _-=w*(ed[u]^ed[v]);
    assert(!_);
}
```

5.17 点双

一些结论：

判定一个图里是否有（点不重复）偶环：看其所有点双，若存在点数为偶数的或边数多于点数的点双，则存在偶环。

（无自环时）点双的边不交，边双的点不交。点双内的总点数 $O(n)$，总边数为 m，边双内的总点数为 n，总边数不超过 m。

构造函数传入邻接表和边数，其中 pair 的 second 是边的标号。

所有标号从 0 开始。

不能处理有自环的情况，因为此时点双内的总边数不是线性的。

bcc_node：每个点双包含的点（已验证）；bcc_edge：每个点双包含的边；bcc_n：新图点数；ct：是否割点（已验证）；blk：边所属点双标号。

```
struct node_bcc
{
    int n, id, tp, bcc_n;
    vector<vector<pair<int, int>>> e;
    vector<vector<int>> bcc_node, bcc_edge;
    vector<int> dfn, low, st, ed, blk, ct;
    node_bcc(const vector<vector<pair<int, int>>> &e, int m) :

}
```

5.22 无向图最小环

原理：floyd 外层循环本质是计算只经过 $\le k$ 的点的最短路。因此枚举环上标号最大的，在做这一轮转移之前正好是不经过它的最短路。

$O(n^3)$，$O(n^2)$。

```
int f[N][N],jl[N][N];
int n,m,c,ans=inf,i,j,k,x,y,z;
int main()
{
    read(n);read(m);
    memset(f,0x3f,sizeof(f));
    memset(jl,0x3f,sizeof(jl));
    while (m--)
    {
        read(x);read(y);read(z);
        jl[x][y]=jl[y][x]=f[x][y]=f[y][x]=min(f[y][x],z);
    }
    for (k=1;k<=n;k++)
    {
        for (i=1;i<k;i++) if (jl[k][i]!=jl[0][0]) for (j=1;j<i;j++)
            if (jl[k][j]!=jl[0][0]) ans=min(ans,jl[k][i]+jl[k][j]+f[i][j]);
        for (i=1;i<=n;i++) if (i!=k) for (j=1;j<=n;j++)
            if ((j!=i)&&(j!=k)) f[i][j]=min(f[i][j],f[i][k]+f[k][j]);
```

```
    }
    if (ans==inf) puts("No␣solution."); else printf("%d",ans);
}
```

5.23 切比雪夫距离最小生成树

原理：先转曼哈顿距离，再用曼哈顿的板子。

$O(n\log n)$，$O(n)$。

```
const int N=3e5+2,M=N<<2;
struct P
{
    int u,v,w;

    }
}
using LCA::lca, LCA::fun, LCA::dis;
```

5.31 换根树剖

本质是对普通树剖在换根后的子树进行分类讨论。
设预处理的根是 u，当前根是 v，那么 w 的子树如下：

1. $w=v$，dfn 区间为 $[1,n]$。
2. w 在 u,v 之间，dfn 区间为 $[1,n]$ 去掉 w 前往 v 方向的子树。找到这个子树的方法见 find 函数。
3. 其余情况，dfn 区间和原来一致。

$O(n+q\log n)$，$O(n)$。

```
void dfs1(int x)
{
    int i;
    siz[x]=1;
    for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x])
    {
        dep[lj[i]]=dep[f[lj[i]]=x]+1;
        dfs1(lj[i]);
        siz[x]+=siz[lj[i]];
        if (siz[hc[x]]<siz[lj[i]]) hc[x]=lj[i];
    }
}
void dfs2(int x)
{
    nfd[dfn[x]=++bs]=x;
```

```
    if (hc[x])
    {
        int i;
        top[hc[x]]=top[x];
        dfs2(hc[x]);
        for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x])) dfs2(top[lj[i]]=lj[i]);
    }
}
void mdf(int xx,int yy)
{
    while (top[xx]!=top[yy])
    {
        if (dep[top[xx]]<dep[top[yy]]) swap(xx,yy);
        z=dfn[top[xx]];y=dfn[xx];xdsmdf(1);
        xx=f[top[xx]];
    }
    if (dep[xx]>dep[yy]) swap(xx,yy);
    z=dfn[xx];y=dfn[yy];
    xdsmdf(1);
}
int find(int x,int y)//找到 y 向 x 的子树
{
    while ((top[x]!=top[y])&&(f[top[x]]!=y)) x=f[top[x]];
    if (top[x]==top[y]) return hc[y];
    return top[x];
}
int main()
{
    read(n);read(m);
    for (i=2;i<=n;i++)
    {
        read(x);read(y);
        add();
    }bs=0;
    for (i=1;i<=n;i++) read(v[i]);
    dfs1(dep[1]=1);dfs2(top[1]=1);

        }
        printf("%d\n",dt);
    }
}
```

5.32 树上启发式合并，DSU on tree

一种过时的、基于两次 dfs 的写法，在复杂度要求不严时不如直接存储 set。

流程：

1. dfs 轻子树计算答案，并清空全局统计信息。
2. dfs 重子树统计答案和全局信息。
3. dfs 轻子树统计全局信息。

```
void dfs1(int x)
{
    siz[x]=zdep[x]=1;
    int i;
    for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x])
    {
        dep[lj[i]]=dep[f[lj[i]]=x]+1;
        dfs1(lj[i]);
        siz[x]+=siz[lj[i]];
        if (siz[hc[x]]<siz[lj[i]]) hc[x]=lj[i];
        zdep[x]=max(zdep[x],zdep[lj[i]]+1);
    }
}
void cal(int x)
{
    int i;
    dl[tou=wei=1]=x;
    while (tou<=wei)
    {
        ++dp[dep[x=dl[tou++]]];
        if ((dp[dep[x]]>dp[zd])||(dp[dep[x]]==dp[zd])&&(dep[x]<zd)) zd=dep[x];
        for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x]) dl[++wei]=lj[i];
    }
}
void dfs2(int x)
{
    if (!hc[x])
    {
        if (++dp[dep[x]]>dp[zd]) zd=dep[x];
        return;
    }
    int i;
    for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x]))
    {
        dfs2(lj[i]);
        memset(dp+dep[lj[i]],0,zdep[lj[i]]<<2);
```

```
    }
    dfs2(hc[x]);
    dp[dep[x]]=1;
    if (dp[zd]<=1) zd=dep[x];
    for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x])) cal(lj[i]);
    ans[x]=zd-dep[x];
}
```

5.33 长链剖分（k 级祖先）

$O(n\log n+q)$，$O(n)$。

```
void dfs1(int x)
{
    int i;
    for (i=1;i<=er[dep[x]-1];i++) f[x][i]=f[f[x][i-1]][i-1];md[x]=dep[x];
    for (i=fir[x];i;i=nxt[i]) {dep[lj[i]]=dep[x]+1;dfs1(lj[i]);if (md[lj[i]]>md[dc[x]]) dc[x]=lj[i
        ];}
    if (dc[x]) md[x]=md[dc[x]];
}
void dfs2(int x)
{
    int i;
    if (dc[x])
    {
        top[dc[x]]=top[x];
        dfs2(dc[x]);
        for (i=fir[x];i;i=nxt[i]) if (lj[i]!=dc[x]) dfs2(top[lj[i]]=lj[i]);
    }
    if (x==top[x])
    {
        c=md[x]-dep[x];y=x;up[x].push_back(x);down[x].push_back(x);
        for (i=1;(i<=c)&&(y=f[y][0]);i++) up[x].push_back(y);y=x;
        for (i=1;i<=c;i++) down[x].push_back(y=dc[y]);
    }
}
int main()
{
    int n,q,ans=0,x,y,c,i;
    ll ta=0;
    read(n);read(q);read(s);
    for (i=1;i<=n;i++) {read(f[i][0]);if (f[i][0]==0) rt=i; else add(f[i][0],i);}
    for (i=2;i<=n;i++) er[i]=er[i>>1]+1;dep[rt]=1;
    dfs1(rt);dfs2(top[rt]=rt);
    for (i=1;i<=q;i++)
    {
        x=(get(s)^ans)%n+1;y=(get(s)^ans)%dep[x];
        //此时计算 x 的 y 级祖先。结果在 ans 中。
        if (y==0) {ans=x;ta^=(ll)i*ans;continue;}
        c=dep[x]-y;x=top[f[x][er[y]]];
        if (dep[x]>c) ans=up[x][dep[x]-c]; else ans=down[x][c-dep[x]];
        ta^=(ll)i*ans;
    }
    printf("%lld",ta);
}
```

5.34 长链剖分（dp 合并）

一种常见的实现方法是用指针指向同一片数组区域，使得从链头到链尾正好指向连续的一段数组，就不需要计算偏移量了。

$O(n)$，$O(n)$。

```
void dfs1(int x)
{
    top[x]=1;
    for (int i=fir[x];i;i=nxt[i]) if (!top[lj[i]])
    {
        dfs1(lj[i]);
        if (len[lj[i]]>len[hc[x]]) hc[x]=lj[i];
    }
    len[x]=len[hc[x]]+1;top[hc[x]]=0;
}
void dfs2(int x)
{
    *f[x]=1;gs[x]=1;
    if (!hc[x]) return;
    ed[x]=1;f[hc[x]]=f[x]+1;
    for (int i=fir[x];i;i=nxt[i]) if (!ed[lj[i]]) dfs2(lj[i]);
    ans[x]=ans[hc[x]]+1;gs[x]=gs[hc[x]];
    if (gs[x]==1) ans[x]=0;
    for (int i=fir[x];i;i=nxt[i]) if ((!ed[lj[i]])&&(lj[i]!=hc[x]))
    {
        int v=lj[i],*p;
        for (int j=0;j<len[v];j++)
        {
            *(p=f[x]+j+1)+=*(f[v]+j);
            if (j+1==ans[x]) {gs[x]=*p;continue;}
            if ((*p>gs[x])||(*p==gs[x])&&(j+1<ans[x])) {gs[x]=*p;ans[x]=j+1;}
        }
    }

5.37 虚树

传入点标号列表，返回虚树边表。自动认为 1 是根，标号从 1 开始。

需要注意的是：在清空的时候需要同时考虑点列表和边表，都清空一下。

你需要提供的是：dep, lca, dfn。

$O(n+\sum k\log n)$，$O(n)$。

```
vector<pair<int, int>> get_tree(vector<int> a)
{
    vector<pair<int, int>> edges;
    sort(all(a), [&](int u, int v) { return dfn[u]<dfn[v]; });
    vector<int> st(a.size()+2);
    int tp=0;
    auto ins=[&](int u)
        {
            if (tp==0)
            {
                st[tp=1]=u;
                return;
            }
            int v=lca(st[tp], u);
            while (tp>1&&dep[v]<dep[st[tp-1]])
            {
                edges.emplace_back(st[tp-1], st[tp]);
                --tp;
            }
            if (dep[v]<dep[st[tp]]) edges.emplace_back(v, st[tp--]);
            if (!tp||st[tp]!=v) st[++tp]=v;
            st[++tp]=u;
        };
    if (a[0]!=1) st[tp=1]=1;//先行添加根节点
    for (int u:a) ins(u);
    if (tp) while (--tp) edges.emplace_back(st[tp], st[tp+1]);//回溯
    return edges;
}
```

5.38 圆方树

题意：求仙人掌上两点最短路。

5.42 最小乘积生成树

题意：每条边有两个属性 x_i, y_i，你需要最小化 $(\sum x_i)(\sum y_i)$。

你需要实现的是 sol1，即按照 val 为权值的答案。val_i 是根据 x_i, y_i 计算的。

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
const int N=202,M=10002;
struct P
{
    int x,y;
    P(int a=0,int b=0):x(a),y(b){}
    bool operator<(const P &o) const {return (ll)x*y<(ll)o.x*o.y||(ll)x*y==(ll)o.x*o.y&&x<o.x;}
};
struct Q
{
    int u,v,x,y,val;
    bool operator<(const Q &o) const {return val<o.val;}
};
P ans=P(1e9,1e9),l,r;
Q a[M];
int f[N];
int n,m,i;
int getf(int x)
{
    if (f[x]==x) return x;
    return f[x]=getf(f[x]);
}
P sol1()
{
    P r=P(0,0);
    for (i=1;i<=n;i++) f[i]=i;
    sort(a+1,a+m+1);
    for (i=1;i<=m;i++) if (getf(a[i].u)!=getf(a[i].v))
    {
        f[f[a[i].u]]=f[a[i].v];
        r.x+=a[i].x,r.y+=a[i].y;
    }
    return r;
}
void sol2(P l,P r)
{
    for (i=1;i<=m;i++) a[i].val=(r.x-l.x)*a[i].y+(l.y-r.y)*a[i].x;
    P np=sol1();
    ans=min(ans,np);
    if ((ll)(r.x-l.x)*(np.y-l.y)-(ll)(r.y-l.y)*(np.x-l.x)>=0) return;
    sol2(l,np);sol2(np,r);
}
int main()
{
    read(n);read(m);
    for (i=1;i<=m;i++) read(a[i].u),read(a[i].v),read(a[i].x),read(a[i].y),++a[i].u,++a[i].v;
    for (i=1;i<=m;i++) a[i].val=a[i].x;l=sol1();
```

```
    for (i=1;i<=m;i++) a[i].val=a[i].y;r=sol1();
    ans=min(ans,min(l,r));sol2(l,r);
    printf("%d␣%d",ans.x,ans.y);
}
```

5.43 最小斯坦纳树

题意：让给定点集连通的最小生成树（不要求全图连通）

$O(3^k n + 2^k m \log m)$。

```
const int N=102,M=1002,K=1024;
typedef long long ll;
typedef pair<ll,int> pa;
priority_queue<pa,vector<pa>,greater<pa> > heap;
pa cr;
ll f[K][N],inf;
int lj[M],len[M],nxt[M],fir[N];
int n,m,q,i,j,k,x,y,z,bs,c;
void add()
{
    lj[++bs]=y;
    len[bs]=z;
    nxt[bs]=fir[x];
    fir[x]=bs;
    lj[++bs]=x;
    len[bs]=z;
    nxt[bs]=fir[y];
    fir[y]=bs;
}
void dijk(int s)
{
    int i;
    while (!heap.empty())
    {
        x=heap.top().second;heap.pop();
        for (i=fir[x];i;i=nxt[i]) if (f[s][lj[i]]>f[s][x]+len[i])
        {
            cr.first=f[s][cr.second=lj[i]]=f[s][x]+len[i];
            heap.push(cr);
        }
        while ((!heap.empty())&&(heap.top().first!=f[s][heap.top().second])) heap.pop();
    }
}
int main()
{
    memset(f,0x3f,sizeof(f));inf=f[0][0];
    read(n);read(m);read(q);
    while (m--)
    {
        read(x);read(y);read(z);
        add();
    }
    for (i=1;i<=q;i++)
    {
        read(x);
        f[1<<i-1][x]=0;
```

```
    }
    q=(1<<q)-1;
    for (i=1;i<=q;i++)
    {
        for (k=1;k<=n;k++)
        {
            for (j=i&(i-1);j;j=i&(j-1)) f[i][k]=min(f[i][k],f[j][k]+f[i^j][k]);
            if (f[i][k]<inf) heap.push(pa(f[i][k],k));
        }
        dijk(i);
    }
    for (i=1;i<=n;i++) inf=min(inf,f[q][i]);
    printf("%lld",inf);
}
```

5.44 2-sat

支持添加一个条件 add(u,x,v,y)，表示 $a_u = x \Rightarrow a_v = y$。支持设定一个变量的值。

$O(n+m)$，$O(n+m)$。

```
struct sat
{
    vector<vector<int>> e;
    vector<int> dfn,low,st,f,ed;
    int fs,tp,id,n;
    sat(int n):n(n),e(n*2),dfn(n*2,-1),low(n*2),st(n*2),f(n*2,-1),ed(n*2),fs(0),tp(-1),id(0){}
    void dfs(int u)
    {
        dfn[u]=low[u]=id++;
        ed[u]=1;st[++tp]=u;
        for (int v:e[u]) if (dfn[v]!=-1)
        {
            if (ed[v]) low[u]=min(low[u],dfn[v]);
        } else dfs(v),low[u]=min(low[u],low[v]);
        if (dfn[u]==low[u])
        {
            do
            {
                f[st[tp]]=fs;
                ed[st[tp]]=0;
            } while (st[tp--]!=u);
            ++fs;
        }
    }
    void add(int u,bool x,int v,bool y)
    {
        assert(u>=0&&u<n&&v>=0&&v<n);
        e[u+x*n].push_back(v+y*n);
        e[v+(y^1)*n].push_back(u+(x^1)*n);
    }
    void set(int u,bool x)
    {
        assert(u>=0&&u<n);
        e[u+(x^1)*n].push_back(u+x*n);
    }
    vector<int> getans()
```

```
    {
        int i;
        for (i=0;i<n*2;i++) if (dfn[i]==-1) dfs(i);
        vector<int> r(n);
        for (i=0;i<n;i++)
        {
            if (f[i]==f[i+n]) return {};
            r[i]=f[i]>f[i+n];
        }
        return r;
    }
};
```

5.45 Kosaraju 强连通分量（bitset 优化）

实用意义不大。

$O(\frac{n^2}{w})$，$O(\frac{n^2}{w})$。

```
void dfs1(int x)
{
    int i;ed[x]=0;
    for (i=(lj[x]&ed)._Find_first();i<=n;i=(lj[x]&ed)._Find_next(i)) dfs1(i);
    sx[--tp]=x;
}
void dfs2(int x)
{
    int i;ed[x]=0;tv[f[x]=f[0]]+=v[x];
    for (i=(fj[x]&ed)._Find_first();i<=n;i=(fj[x]&ed)._Find_next(i)) dfs2(i);
}
int main()
{
    read(n);read(m);tp=n+1;
    for (i=1;i<=n;i++) {ed[i]=1;read(v[i]);}
    for (i=1;i<=m;i++)
    {
        read(x);read(y);lj[x][y]=1;fj[y][x]=1;lb[i][0]=x;lb[i][1]=y;
    }
    for (i=1;i<=n;i++) if (ed[i]) dfs1(i);
    ed.set();
    for (i=1;i<=n;i++) if (ed[sx[i]]) {++f[0];dfs2(sx[i]);}
    for (i=1;i<=m;i++) if (f[lb[i][0]]!=f[lb[i][1]])
    {
        flj[f[lb[i][0]]].push_back(f[lb[i][1]]);++rd[f[lb[i][1]]];
    }
    for (i=1;i<=f[0];i++) if (!rd[i]) dl[++wei]=i;

5.50 有向图欧拉回路计数（BEST 定理）/生成树计数

$O(n^3)$，$O(n^2)$。

以 u 为起点的欧拉回路个数 $sum = T(u) \times \prod_{v=1}^{n}(out(v)-1)!$，其中 $T(u)$ 是以 u 为根的内向树

个数（出度矩阵-邻接矩阵），$out(v)$ 是 v 的出度。若允许循环同构（如 $1 \to 2 \to 1 \to 3 \to 1$ 与 $1 \to 3 \to 1 \to 2 \to 1$），还需多乘 $out(u)$。

这里的部分代码是未经验证的。

```

    return r;
```

```
}
```

6 计算几何

6.1 自适应 simpson 法

sim(l,r) 计算 $\int_l^r f(x)\,\mathrm{d}x$

```
const db eps=1e-7;
db sl,sr,sm,a;
db f(db x)
{
    return pow(x,a/x-x);
}
db g(db l,db r)
{
    db mid=(l+r)*0.5;
    return (f(l)+f(r)+f(mid)*4)/6*(r-l);
}
db sim(db l,db r)
{
    db mid=(l+r)*0.5;
    sl=g(l,mid);sr=g(mid,r);sm=g(l,r);
    if (abs(sl+sr-sm)<eps) return sl+sr;
    return sim(l,mid)+sim(mid,r);
}
```

6.2 计算几何全

功能其实比较少，因为实际遇到的几何题不多。最有用的可能是闵可夫斯基和合并凸包，和常规的线段判交之类的。其余功能最好直接使用 HDU 板。

```
namespace geometry//不要用 int!
{
#define tmpl template<class T>
    typedef long long ll;
    typedef long double db;
    const db eps=1e-6;
#define all(x) (x).begin(),(x).end()
    inline int sgn(const ll &x)
    {
        if (x<0) return -1;
        return x>0;
    }
    inline int sgn(const db &x)
    {
        if (fabs(x)<eps) return 0;
        return x>0?1:-1;
    }
    tmpl struct point//* 为叉乘，& 为点乘，只允许使用 (long )double 和 ll
    {

```

7 公式与杂项

7.1 枚举大小为 k 的集合

思路：通过进位创造 1，再把一串 1 移到最后。

```
for (int s=(1<<k)-1,t;s<1<<n;t=s+(s&-s),s=(s&~t)>>__lg(s&-s)+1|t)
{}
```

7.2 min plus 卷积

计算 $c_i=\min_{j=0}^{i} a_j+b_{i-j}$。

要求 b 是凸的，即 $b_{i+1}-b_i$ 不降。

```
template <class T> vector<T> min_plus_convolution(const vector<T> &a,const vector<T> &b)
{
    int n=a.size(),m=b.size(),i;
    vector<T> c(n+m-1);
    function<void(int,int,int,int)> dfs=[&](int l,int r,int ql,int qr)
        {
            if (l>r) return;
            int mid=l+r>>1;
            while (ql+m<=l) ++ql;
            while (qr>r) --qr;
            int qmid=-1;
            c[mid]=inf;
            for (int i=ql; i<=qr; i++) if (mid-i>=0&&mid-i<m&&cmin(c[mid],a[i]+b[mid-i])) qmid=i;
            dfs(l,mid-1,ql,qmid);
            dfs(mid+1,r,qmid,qr);
        };
    dfs(0,n+m-2,0,n-1);
    return c;
}
```

7.3 所有区间 GCD

需要自定义 fun，如 gcd，and，or。

```
template<class T> struct GCD
{
    vector<pair<int, T>> res;
    GCD(const vector<T> &a):res(n)
    {
        int n=a.size(), i, j;
        vector<ll> v(n);
        vector<int> l(n);
        vector<vector<pair<int, T>> res(n);
        for (i=0; i<n; i++)
        {
            for (v[i]=a[i], j=l[i]=i; j>=0; j=l[j]-1)
            {
                v[j]=fun(v[j], a[i]);
                while (l[j]&&fun(a[i], v[l[j]-1])==fun(a[i], v[j])) l[j]=l[l[j]-1];
                //[l[j]..j,i]区间内的值求 fun 均为 v[j]
            }
```

```
        for (j=i; j>=0; j=l[j]) res[i].push_back({l[j], v[j]});
        reverse(all(res[i]));
      }
    }
    T ask(int l, int r)//[l,r]
    {
      return res[r].prev(upper_bound(l))->second;
    }
};
```

7.4 整体二分（区间 k-th）

$O((n+q)\log a)$，$O(n+q)$。

```
struct cz
{
    int x,y,kth,pos,typ;
};

7.7 分散层叠算法（Fractional Cascading）

$O(n+q(k+\log n))$，$O(n)$。
给出 k 个长度为 n 的有序数组。
现在有 q 个查询: 给出数 x，分别求出每个数组中大于等于 x 的最小的数 (非严格后继)。
若后继不存在，则定义为 0。你需要在线地回答这些询问。

```
int a[M][N],b[M][N<<1],c[M][N<<1][2],len[M],ans[M];
int n,m,qs,p,q,d,i,j,x,y,la;
int main()
{
    read(n);read(m);read(qs);read(d);
    for (j=1;j<=m;j++) for (i=0;i<n;i++) read(a[j][i]);
    for (j=1;j<=m;j++) a[j][n]=inf+j;++n;
    for (i=0;i<n;i++) b[m][i]=a[m][i],c[m][i][0]=i;
    len[m]=n;
    for (j=m-1;j;j--)
    {
        p=0,q=1;
        while (p<n&&q<len[j+1])
        if (a[j][p]<b[j+1][q]) b[j][len[j]]=a[j][p],c[j][len[j]][0]=p++,c[j][len[j]++][1]=q;
        else b[j][len[j]]=b[j+1][q],c[j][len[j]][0]=p,c[j][len[j]++][1]=q,q+=2;
        while (p<n) b[j][len[j]]=a[j][p],c[j][len[j]][0]=p++,c[j][len[j]++][1]=q;
        while (q<len[j+1]) b[j][len[j]]=b[j+1][q],c[j][len[j]][0]=p,c[j][len[j]++][1]=q,q+=2;
    }
    for (int ii=1;ii<=qs;ii++)
    {
        read(x);x^=la;
        y=lower_bound(b[1],b[1]+len[1],x)-b[1];
        ans[1]=a[1][c[1][y][0]];y=c[1][y][1];//下标是c[1][y][0]
        for (j=2;j<=m;j++)
        {
            if (y&&b[j][y-1]>=x) --y;
```

```
            ans[j]=a[j][c[j][y][0]];//下标是c[j][y][0]
            y=c[j][y][1];
        }
        la=0;
        for (i=1;i<=m;i++) la^=ans[i]>inf?0:ans[i];
        if (ii%d==0) printf("%d\n",la);
    }
}
```

7.8 圆上整点（二平方和定理）

$x^2+y^2=n$ 的整数解的数目的四分之一 $f(n)$ 是积性数论函数，且对于**素数幂**有：$f(p^k)=\begin{cases}1 & p=2\\ k+1 & p\equiv 1 \pmod 4\\ (k+1) \bmod 2 & p\equiv 3 \pmod 4\end{cases}$

以下代码给出所有的非负整数解。注意非负整数解个数不等于 $f(n)$。

时间复杂度为 $O(n^{\frac{1}{4}}+f(n))$，其中 $O(n^{\frac{1}{4}})$ 是 pollard-rho 的复杂度。

$f(n)$ 的量级不好分析，但不会超过约数个数 $O(d(n))\approx O(n^{\frac{1}{3}})$，且可以推测不能达到。实践上 10^{18} 以内 $f(n)\le 3072$。

}
```

7.9 模意义真分数还原

没啥用。

$q \equiv \frac{x}{a} \pmod{p}$，$|a| \leq A$。

```
pair<int, int> approx(int p,int q,int A)
{
    int x=q,y=p,a=1,b=0;
    while (x>A)
    {
        swap(x,y);swap(a,b);
        a-=x/y*b;x%=y;
    }
    return make_pair(x,a);
}
```

7.10 快速取模

```
__uint128_t brt=((__uint128_t)1<<64)/mod;
for(int i=1;i<=n;i++)
{
    ans*=i;
    ans=ans-mod*(brt*ans>>64);
    while(ans>=mod) ans-=mod;//可以替换为 if，但据说会变慢。如果循环展开则需要替换
}

struct barret{
    ll p,m; //p 表示上面的模数，m 为取模参数
    int c=0;
    inline void init(ll t){
        c=48+log2(t),p=t;
        m=(ll((ulll(1)<<c)/t));
    }
    friend inline ll operator % (ll n,const barret &d) { // get n % d
        return n-((ulll(n)*d.m)>>d.c)*d.p;
    }
}modp;
```

7.11 IO 优化

7.11.1 WDOI

```
class fast_iostream{
private:
    const int MAXBF = 1 << 20; FILE *inf, *ouf;
    char *inbuf, *inst, *ined;
    char *oubuf, *oust, *oued;
    inline void _flush(){fwrite(oubuf, 1, oued - oust, ouf);}
    inline char _getchar(){
        if(inst == ined) inst = inbuf, ined = inbuf + fread(inbuf, 1, MAXBF, inf);
        return inst == ined ? EOF : *inst++;
    }
    inline void _putchar(char c){
        if(oued == oust + MAXBF) _flush(), oued = oubuf;
        *oued++ = c;
    }
public:
     fast_iostream(FILE *_inf = stdin, FILE * _ouf = stdout)
    :inbuf(new char[MAXBF]), inf(_inf), inst(inbuf), ined(inbuf),
     oubuf(new char[MAXBF]), ouf(_ouf), oust(oubuf), oued(oubuf){}
    ~fast_iostream(){_flush(); delete inbuf; delete oubuf;}
    template <class Int>
    fast_iostream& operator >> (Int &n){
        static char c;
        while((c = _getchar()) < '0' || c > '9');n = c - '0';
        while((c = _getchar()) >='0' && c <='9') n = n * 10 + c - '0';
        return *this;
    }
    template <class Int>
    fast_iostream& operator << (Int n){
        if(n < 0) _putchar('-'), n = -n; static char S[20]; int t = 0;
        do{S[t++] = '0' + n % 10, n /= 10;} while(n);
        for(int i = 0;i < t;++i) _putchar(S[t - i - 1]);
        return *this;
    }
    fast_iostream& operator << (char c){_putchar(c); return *this;}
    fast_iostream& operator << (const char *s){
        for(int i = 0;s[i];++i) _putchar(s[i]); return *this;
    }
}fio;//unsigned
```

7.11.2 自用

```
c[fread(c+1,1,N,stdin)+1]=0;char *cc=c;
void read(int &x)
{
    char *c=cc;
    while ((*c<48)||(*c>57)) ++c;
    x=*(c++)^48;
    while ((*c>=48)&&(*c<=57)) x=x*10+(*(c++)^48);cc=c;
}
void read(int &x)
{
    char *c=cc;fh=1;
    while ((*c<48)||(*c>57)){if (*c=='-') {++c;fh=-1;break;}++c;}
    x=*(c++)^48;
    while ((*c>=48)&&(*c<=57)) x=x*10+(*(c++)^48);
```

```
    x*=fh;cc=c;
}
void write(const int x)
{
    while (x)
    {
        st[++tp]=x%10;
        x/=10;
    }
    char *c=nc;
    while (tp) *(++c)=st[tp--]|48;
    *(++c)=10;nc=c;
}
    char *nc=sc;
    fwrite(sc+1,1,stp,stdout);
```

7.12 手动开栈

一种写法是文件开头放，但部分 OJ 会失效。

```
#pragma comment(linker, "/STACK:102400000,102400000")
```

另一种写法是在 main 开头写，但必须以 exit(0) 结束程序。
以下两个应该有一个是对的，不对会 CE。

```
{
    static int OP = 0;
    if (OP++ == 0)
    {
        int size = 256 << 20; // 256MB
        char *p = (char *)malloc(size) + size;
        __asm__("movl %0, %%esp\n" :: "r"(p));
    }
}
{
    static int OP=0;
    if (OP++==0)
    {
        int size=128<<20;//128MB
        char* p=new char[size]+size;
        __asm__ __volatile__("movq %0, %%rsp\n""pushq $exit\n""jmp main\n"::"r"(p));
    }
}
```

7.13 德扑

solve 返回按照出现次数排序的 vector<int>（0 下标处为牌型），这样就可以字典序比较了。

```
struct Q
{
    int suit, rank;
    bool operator<(const Q &o) const { return pair{rank, suit}<pair{o.rank, o.suit}; }
    bool operator==(const Q &o) const { return pair{rank, suit}==pair{o.rank, o.suit}; }
};
auto solve=[&](vector<Q> a)
{
```

```
    vector<int> res;
    vector<int> cnt(15);
    for (auto [s, r]:a) ++cnt[r];
    sort(all(a));
    int i;
    bool is_flush=1, is_str=0;
    for (i=1; i<5; i++) is_flush&=a[i].suit==a[0].suit;
    is_str=*max_element(all(cnt))==1&&a[0].rank+4==a[4].rank;
    vector<int> b(6);
    for (i=1; i<6; i++) b[i]=a[i-1].rank;
    sort(1+all(b), [&](int x, int y)
        {
            return pair{cnt[x], x}>pair{cnt[y], y};
        });
    if (b==vector{0, 12, 3, 2, 1, 0}) is_str=1, b[1]=0;
    if (is_flush&&is_str) return b[0]=9, b;
    if (cnt[b[1]]==4) return b[0]=8, b;
    if (cnt[b[1]]==3&&cnt[b[4]]==2) return b[0]=7, b;
    if (is_flush) return b[0]=6, b;
    if (is_str) return b[0]=5, b;
    if (cnt[b[1]]==3) return b[0]=4, b;
    if (cnt[b[1]]==2&&cnt[b[3]]==2) return b[0]=3, b;
    if (cnt[b[1]]==2) return b[0]=2, b;
    return b;
};
auto turn=[&](string s)
{
    Q res=Q{"SHDC"s.find(s[0]), "23456789TJQKA"s.find(s[1])};
    return res;
};
```

7.16 公式

向上取整的整除分块 $[i, \lfloor \frac{n-1}{\lceil \frac{n}{i} \rceil - 1} \rfloor]$

n 个点 k 个连通块的生成树方案 $n^{k-2}\prod\limits_{i=1}^{k} siz_i$

(x,y) 曼哈顿距离 $\rightarrow (x+y,x-y)$ 切比雪夫距离 (x,y) 切比雪夫距离 $\rightarrow (\dfrac{x+y}{2},\dfrac{x-y}{2})$ 曼哈顿距离

错排数 $=\lceil 0.5+\frac{n!}{e}\rceil$

Kummer's Theorem: $\binom{n+m}{n}$ 含 p $(p\in \mathrm{prime})$ 的次数是 $n+m$ 在 p 进制下的进位数

$\ln(1-x^V)=-\sum\limits_{i\geq 1}\dfrac{x^{Vi}}{i}$

$x^{\bar{n}}=\sum\limits_{i} S_1(n,i)x^i$

$$\begin{cases} x\equiv a_1 \pmod{m_1}\\ x\equiv a_2 \pmod{m_2}\\ \cdots \\ x\equiv a_n \pmod{m_n}\end{cases}$$

m_i 为不同的质数。设 $M=\prod\limits_{i=1}^{n} m_i$，$t_i\times\dfrac{M}{m_i}\equiv 1 \pmod{m_i}$，则 $x\equiv\sum\limits_{i=1}^{n} a_i t_i \dfrac{M}{m_i}$。

$V-E+F=2$，$S=n+\frac{s}{2}-1$。（n 为内部，s 为边上）

用途：对于相邻的不相等的值，在中间画一条线（最外也画），连通块个数 $=1+E-V+$ 内部框个数

注意全都是不含矩形边界上的。

五边形数 GF：$\frac{x(2x+1)}{(1-x)^3}$

五边形数：$\frac{3n^2-n}{2}$，广义含非正，逆为分拆数 GF（注意系数正负和 n 取值奇偶性相同）

贝尔数（划分集合方案数）EGF：$\exp(e^x-1)$，$B_n=\sum\limits_{i=0}^{n} S_2(n,i)$，伯努利数 EGF：$\dfrac{x}{e^x-1}$

$S_1(i,m)$ EGF：$\dfrac{(\sum\limits_{i\geq 0}\dfrac{x^i}{i})^m}{m!}$，$S_2(i,m)$ EGF：$\dfrac{(e^x-1)^m}{m!}$

多项式牛顿迭代：如果已知 $G(F(x))\equiv 0 \pmod{x^{2n}}$，$G(F_*(x))\equiv 0 \pmod{x^n}$，则有 $F(x)\equiv F_*(x)-\frac{G(F_*(x))}{G'(F_*(x))} \pmod{x^{2n}}$。求导时孤立的多项式视为常数。

$\int_0^1 t^a(1-t)^b\mathrm{d}t=\dfrac{a!b!}{(a+b+1)!}$，$\sum\limits_{i=0}^{n-1} i^{\underline{k}}=\dfrac{n^{\underline{k+1}}}{k+1}$

Burnside 引理：等价类数量为 $\sum\limits_{g\in G}\dfrac{X^g}{|G|}$，$X^g$ 表示 g 变换下不动点的数量。

Polya 定理：染色方案数为 $\sum\limits_{g\in G}\dfrac{m^{c(g)}}{|G|}$，其中 $c(g)$ 表示 g 变换下环的数量。

矩阵树定理：有向图内向生成树个数计算用出度矩阵-邻接矩阵

假设已经只保留了一个牛人酋长，其名字为 $A=a_1a_2\cdots a_l$。

假设王国旁边开了一座赌场，每单位时间（就称为“秒”吧）会有一个赌徒带着 1 铜币进入赌场。

赌场规则很简单：支付 x 铜币赌下一秒会唱出 y，如果猜对了就返还 nx 铜币，否则钱就没了。

每个赌徒会如下行动：支付 1 铜币赌下一秒会唱出 a_1，如果赌对了就支付得到的 n 铜币赌下一秒会唱出 a_2，如果还对了就支付得到的 n^2 铜币赌下一秒会唱出 a_3，等等，以此类推，最后支付 n^{l-1} 铜币赌下一秒会唱出 a_l。

一旦连续唱出了 $a_1a_2\cdots a_l$，赌场老板就会认为自己亏大了而关门，并驱散所有赌徒。

那么关门前发生了什么呢？以 $A=\{1,4,1,5,1,1,4,1\},n=5$ 为例：

- 最后一位赌徒拿着 5 铜币离开；- 倒数第三位赌徒拿着 5^3 铜币离开；- 倒数第八位赌徒拿着 5^8 铜币离开；- 其他所有赌徒空手而归。

我们可以发现 1,3 恰好是原序列的所有 border 的长度，而且对于其他的名字也有这样的规律。

这时候最神奇的一步来了：由于这个赌博游戏是公平的，因此赌场应该期望下不赚不赔，因此关门时期望来了 $5+5^3+5^8$ 个赌徒，因此期望需要 $5+5^3+5^8$ 单位时间唱出这个名字。

同理，即可知道对于一般的 A，答案为：

$$\sum_{a_1a_2\cdots a_c=a_{l-c+1}a_{l-c+2}\cdots a_l} n^c$$

8 语言基础

8.1 Makefile

```
%:%.cpp %.in
    g++ $< -o $@ -std=c++17 -D_GLIBCXX_DEBUG -D_GLIBCXX_DEBUG_PEDANTIC
    ./$@ < $@.in
```

8.2 初始代码

```
#include "bits/stdc++.h"
using namespace std;
typedef long long ll;
#define all(x) (x).begin(),(x).end()
int main()
{
    ios::sync_with_stdio(0); cin.tie(0);
    int T; cin>>T;
    while (T--)
    {

    }
}
```

8.3 bitset

```
#include <bits/stdc++.h>
using namespace std;
bitset<10> f(12);
char s2[]="100101";
bitset<10> g(s2);
string s="100101";//reverse 了
bitset<10> h(s);
int main()
{
    for (int i=0;i<=9;i++) if (f[i]) printf("1"); else printf("0");puts("");
    for (int i=0;i<=9;i++) if (g[i]) printf("1"); else printf("0");puts("");
    for (int i=0;i<=9;i++) if (h[i]) printf("1"); else printf("0");puts("");
    cout<<h<<endl;
    foo.count();//1的个数
    foo.flip();//全部翻转
    foo.set();//变1
    foo.reset();//变0
    foo.to_string();
    foo.to_ulong();
    foo.to_ullong();
    foo._Find_first();
    foo._Find_next();
    //位运算：<< 变大，>> 变小
}
```

输出：

```
0011000000
1010010000
1010010000
0000100101
```

8.4 pb_ds 和一些奇怪的用法

```
#pragma GCC optimize("Ofast")

8.5 python 使用方法

注意事项：python 容易爆栈，且引用与赋值较为混乱。注意局部变量的 global 怎么写（如果需要修改全局内容）。

文件操作

```
fi = open("discuss.in", "r")
fo = open("discuss.out", "w")
n=int(fi.readline())
fo.write(str(ans))
```

类的构造，重载运算符

```
class Q:
    def __init__(self,x,y):
        self.x=x
        self.y=y
    def __add__(self,o):
        r=Q(self.x+o.x,self.y+o.y)
        return r
    def __sub__(self,o):
        r=Q(self.x-o.x,self.y-o.y)
        return r
    def __mul__(self,o):
```

```
        return self.x*o.y-self.y*o.x
    def __lt__(self,o):
        if self.x!=o.x:
            return self.x<o.x
        return self.y<o.y
n,m=map(int,input().split())
c=list(map(int,input().split()))
print(*c)
a=Q(0,0)
b=Q(1,1)
if a<b-a:
    pass
```

9.11 毛毛虫剖分

毛毛虫剖分，一种由轻重链剖分（HLD）推广而成的树上结点重标号方法，支持修改 / 查询一只毛毛虫的信息，并且可以对毛毛虫的身体和足分别修改 / 查询不同信息.

严格强于树剖，而且复杂度和树剖一样哦！

一些定义（默认在一棵树上）：

毛毛虫：一条链和与这条链邻接的所有结点构成的集合. 虫身（身体）：毛毛虫的链部分. 虫足（足）：毛毛虫除虫身的部分. 重标号方法首先重剖求出重链. DFS，若现在处理到结点 u：若 u 还未被标号，则为其标号. 若 u 是重链头，遍历这条重链，将邻接这条链的结点依次标号. 先递归重儿子，再递归轻儿子. 重标号性质对于重链，除链头外的结点标号连续. 对于任意结点，其轻儿子标号连续. 对于以重链头为根的子树，与这条重链邻接的所有结点标号连续. 这样就可以随便维护毛毛虫信息了，顺便还能维护链信息，子树信息等.

时间复杂度同轻重链剖分.

以 SAM 为例，若我们只保留所有的转移边 (u, v) ，满足到达 u 的路径数目大于到达 v 的路径数目一半，且从 v 出发的路径数目大于从 u 出发的路径数目一半，这样剩余的子图显然会形成若干条链，且每个点恰好在一条链上。这样，我们容易证明，从根结点出发的任何一条路径，至多经过 $O(\log n)$ 条不在链上的转移边（也意味着至多经过 $O(\log n)$ 条链）。

以下是一段示例代码，展示了将一条链对应区间取出来的过程

```

vector<int> e[N];
vector<pair<int, int>> seg[N], qu[N];
int ans[Q];
int dfn[N], dep[N], nfd[N], top[N], f[N], sz[N], hc[N], pre[N], fir[N], lst2[N], rt[N];
int
void insert()
void dfs1(int u)
{
    sz[u] = 1;
    for (int v : e[u]) if (v != f[u])
    {
        dep[v] = dep[u] + 1;
        f[v] = u;
        dfs1(v);
        sz[u] += sz[v];
        if (sz[v] > sz[hc[u]]) hc[u] = v;
    }
    if (f[u]) erase(e[u], f[u]);
}
void dfs2(int u)
```
