1 前言

# 1 前言

6

此模板的初衷是个人使用,因此已有的模板可能未列出。建议结合 Heltion 模板和 HDU 模板使用。

模板需要的版本为 cpp17 或 cpp20。

大部分情况下,涉及取模的都需要使用 unsigned long long,即使类型名是 11。这是因为值域较大有利于合理减少取模次数。

optional 的用法:一个 optional 变量 r 可以用 if (r) 判断其是否有值。取出值的方法是\*r。常见于包含无解又包含空集解的代码中,便于区分无解和空集解。

常见的被漏掉的初始代码:

常见的缺漏算法:

回文自动机。

2 数据结构 "

## 2 数据结构

#### 2.1 树状数组

支持单点修改、求前缀和、二分前缀和大于等于 x 的第一个位置。 二分这部分没有验证过。

```
template<typename typC> struct bit
   vector<typC> a;
   int n;
   bit() { }
   bit(int nn):n(nn), a(nn+1) { }
   template<typename T> bit(int nn, T *b):n(nn), a(nn+1)
       for (int i=1; i<=n; i++) a[i]=b[i];</pre>
       for (int i=1; i<=n; i++) if (i+(i&-i)<=n) a[i+(i&-i)]+=a[i];</pre>
   void add(int x, typC y)
       //cerr<<"add "<<x<" by "<<y<endl;
       assert(1 \le x \& x \le n);
       a[x] += y;
       while ((x+=x\&-x)<=n) a[x]+=y;
   typC sum(int x)
       //cerr<<"sum "<<x;
       assert(0 \le x \& x \le n);
       typC r=a[x];
       while (x^=x\&-x) r+=a[x];
       //cerr<<"= "<<r<<endl;
       return r;
   typC sum(int x, int y)
       return sum(y)-sum(x-1);
   int lower_bound(typC x)
       if (n==0) return 0;
       int i=__lg(n), j=0;
       for (; i>=0; i--) if ((1<<i|j)<=n&&a[1<<i|j]<x) j|=1<<i, x-=a[j];</pre>
       return j+1;
};
```

### 2.2 线段树

包含标记的线段树,支持线段树上二分,采用左闭右闭。但只支持求左侧第一个符合条件的下标。

要求:具有 info+info, info+=tag, tag+=tag。info, tag 需要有默认构造,但不必有正确的值。

```
template<class info, class tag> struct sgt
```

```
{
   int n, shift;
   info *a;
   info tmp;
   vector<info> s;
   vector<tag> tg;
   vector<int> lz;
   bool flg;
   void build(int x, int 1, int r)
      if (l==r)
         s[x]=(flg?tmp:a[1]);
         return;
      }
      int c=x*2, m=1+r>>1;
      build(c, 1, m); build(c+1, m+1, r);
      s[x]=s[c]+s[c+1];
   }
   flg=0;
      build(1, 1, n);
   sgt(info b, int L, int R):n(R-L+1), shift(L-1), s(R-L+1<<2), tg(R-L+1<<2), lz(R-L+1<<2)
      tmp=b;
      flg=1;
      build(1, 1, n);
   }//[L,R]
   int z, y;
   info res;
   tag dt;
   bool fir;
private:
   void _modify(int x, int 1, int r)
      if (z<=1&&r<=y)</pre>
         s[x] += dt;
         if (lz[x]) tg[x]+=dt; else tg[x]=dt;
         lz[x]=1;
         return;
      }
      int c=x*2, m=1+r>>1;
      if (lz[x])
         if (lz[c]) tg[c]+=tg[x]; else tg[c]=tg[x];
         lz[c]=1; s[c]+=tg[x]; c^=1;
         if (lz[c]) tg[c]+=tg[x]; else tg[c]=tg[x];
         lz[c]=1; s[c]+=tg[x]; c^=1;
         lz[x]=0;
      }
      if (z<=m) _modify(c, 1, m);</pre>
      if (m<y) _modify(c+1, m+1, r);</pre>
      s[x]=s[c]+s[c+1];
```

```
void ask(int x, int 1, int r)
       if (z<=1&&r<=y)</pre>
          res=fir?s[x]:res+s[x];
          fir=0;
          return;
       }
       int c=x*2, m=1+r>>1;

   }
};
```

#### 2.3 珂朵莉树

支持区间赋值、单点访问。维护每个连续段的范围和值。

如果希望维护所有连续段的整体信息(如长度的最大值),修改 add 和 del 函数即可,分别表示连续段被加入和被删去。

特别注意一开始 insert 的不会触发 add, 只有 modify 会触发。

```
namespace chtholly_tree
   using T=int;//可以把 T 修改为任意想要的类型。
   struct node
      int 1;
      mutable int r;
      mutable T v;
      int len() const { return r-l+1; }
      bool operator<(const node &x) const { return l<x.l; }</pre>
   };
   void add(const node &a) {}
   void del(const node &a) {}
   class odt: public set<node>
   public:
       typedef odt::iterator iter;
      iter split(int x)
       {
          iter it=lower_bound({x});
          if (it!=end()&&it->l==x) return it;
          node t=*--it,a=\{t.l,x-1,t.v\},b=\{x,t.r,t.v\};
          del(*it); add(a); add(b);
          erase(it); insert(a);
          return insert(b).first;
      }
      void modify(int l,int r,T v)//[l,r]
          iter lt,rt,it;
          rt=r==rbegin()->r?end():split(r+1); lt=split(l);//[lt,rt)
          while (lt!=begin()&&(it=prev(lt))->v==v) l=(lt=it)->l;
          while (rt!=end()\&\&rt->v==v) r=(rt++)->r;
          for (it=lt; it!=rt; it++) del(*it);
          add(\{1,r,v\});
          erase(lt,rt); insert({1,r,v});
      }
      T operator[](const int x) const { return prev(upper_bound({x}))->v; }//直接访问单点
      iter find(int x) const {return prev(upper_bound({x}));}//找到对应的线段
   };
using chtholly_tree::node,chtholly_tree::odt;
typedef odt::iterator iter;
int main()
   odt s;
   s.insert({0,5,1}); // 先 insert({L,R,x}) 表示整个下标范围和初始值。 左闭右闭。
                    // s={1,1,1,1,1,1,1}
   s.modify(2,3,2); // 左闭右闭。s={1,1,2,2,1,1}
   for (auto [1,r,v]:s)
      //(1,r,v)=(0,1,1)
      //(1,r,v)=(2,3,2)
      //(1,r,v)=(4,5,1)
   }
}
```

! 数据结构 12

#### 2.4 带删堆

本质是额外维护一个堆 q 表示要被删除的元素,当 p 的最值和 q 一样时删除。需要保证每次 pop 的元素都存在于堆中。 本代码的用法和  $priority\_queue$  一致。

```
template<class T, class T1=vector<T>, class T2=less<T>> struct heap
private:
   priority_queue<T, T1, T2> p, q;
   void push(const T &x)
       if (!q.empty()&&q.top()==x)
          q.pop();
          while (!q.empty()&&q.top()==p.top()) p.pop(), q.pop();
       else p.push(x);
   void pop()
   {
      p.pop();
       while (!q.empty()&&p.top()==q.top()) p.pop(), q.pop();
   void pop(const T &x)
       if (p.top()==x)
          p.pop();
          while (!q.empty()&&p.top()==q.top()) p.pop(), q.pop();
       else q.push(x);
   T top() const { return p.top(); }
   int size() const { return p.size()-q.size(); }
   bool empty() const { return p.empty(); }
   vector<T> to_vector() const
       vector<T> a;
       auto P=p, Q=q;
       while (P.size())
          a.push_back(P.top()); P.pop();
          while (Q.size()&&P.top()==Q.top()) P.pop(), Q.pop();
       }
       return a;
};
```

#### 2.5 前 k 大的和

本质是用小根堆维护前 k 大的数, 用大根堆维护其余数。

如果需要支持删除,结合前面一个使用,或者直接用 multiset 进行 extract。

为了方便起见,直接给出支持删除的版本,并且使用 long long。如果不需要支持删除,类型改为优先队列并去掉 pop 函数即可。

注意:复杂度为 O(k-k'), 其中 k' 是上一次询问的 k。也就是说,多组询问时询问的 k 的差值应该尽可能小。

其用法与 priority\_queue 保持一致,可以用同样的方法改写成前 k 小。

```
using ll=long long;
template<class T, class T1=vector<T>, class T2=less<T>> struct ksum_pop
{
private:
   struct __cmp
       bool operator()(const T &x, const T &y) const
          return x!=y&&!T2()(x, y);
       }
   };
   heap<T, T1, __cmp> p;
   heap<T, T1, T2> q;
   11 cur;
public:
   ksum_pop():cur(0) { }
   void push(const T &x)
       if (!q.size()||!T2()(x, q.top())) p.push(x), cur+=x; else q.push(x);
   int size() const { return p.size()+q.size(); }
   void pop(const T &x)
       if (q.size()&&!T2()(q.top(), x)) q.pop(x);
       else p.pop(x), cur-=x;
   11 sum(int k)
       while (p.size()<k)</pre>
          cur+=q.top();
          p.push(q.top());
          q.pop();
       while (p.size()>k)
          cur-=p.top();
          q.push(p.top());
          p.pop();
       return cur;
   }
};
```

### 2.6 可持久化数组

历史遗留产物,无意义,仅作留存,不会更新。 $O((n+q)\log(n))$ , $O((n+q)\log(n))$ 。

```
struct arr
{
   int c[M][2],rt[0],s[M],b[N];
   int ds,n,ver,v,p,i;
```

```
void build(int &x,int 1,int r)
       x=++ds;
       if (l==r) {s[x]=b[1];return;}
       build(c[x][0],1,1+r>>1);
       build(c[x][1],(1+r>>1)+1,r);
   }
   void rebuild(int &x,int pre)
       x=++ds;int l=1,r=n,mid,now=x;
       while (1<r)
          mid=l+r>>1;
          if (mid>=p){c[now][1]=c[pre][1];now=c[now][0]=++ds;r=mid;pre=c[pre][0];} else {c[now]
              ][0]=c[pre][0];now=c[now][1]=++ds;l=mid+1;pre=c[pre][1];}
       s[now] = v;
   void init(int *a,int nn)
       n=nn;
       for (i=1;i<=n;i++) b[i]=a[i];</pre>
       build(rt[0],1,n);
   int mdf(int pv,int pos,int val)
       p=pos,v=val;
       rebuild(rt[++ver],rt[pv]);
       return ver;
   }
   int ask(int ve,int pos)
       int l=1,r=n,x=rt[ve],mid;
       rt[++ver]=rt[ve];
       while (l<r)</pre>
          mid=l+r>>1;
          if (mid>=pos) {x=c[x][0];r=mid;} else {x=c[x][1];l=mid+1;}
       return s[x];
   }
};
```

# 2.7 左偏树/可并堆

建议不要使用。 $pb_ds$  可以替代这个功能。我完全没有使用过这个板子。 $O((n+q)\log n)$ ,O(n)。

```
struct left_tree//小根堆, 大根堆需要改的地方注释了
{
    int j1[N],v[N],f[N],c[N][2],tf[N],n;//tf只有删非堆顶才用
    bool ed[N];
    void init(const int nn,const int *a)
    {
        j1[0]=-1;n=nn;
        memset(j1+1,0,n<<2);
```

```
memset(tf+1,0,n<<2);//同上
       memset(c+1,0,n << 3);
       memset(ed+1,0,n);
       for (int i=1;i<=n;i++) v[f[i]=i]=a[i];</pre>
   int mg(int x,int y)

   }
};
```

### 2.8 树状数组区间加区间求和

```
本质: a_n 区间加等价于差分数组 d_n 的单点加。 \sum_{i=1}^m a_i = \sum_{i=1}^m \sum_{j=1}^i d_j = \sum_{j=1}^m d_j (m-j+1) = ((m+1) \sum_{j=1}^m d_j) - (\sum_{j=1}^m j d_j) \circ 分别维护 d_j 和 jd_j 的前缀和。 O(n) \sim O(q \log n), O(n)。
```

```
struct bit
   ll a[N],b[N],s[N];//有初始值
   int n;
   void init(int nn,int *a)//初始值
       n=nn;s[0]=0;
       for (int i=1;i<=n;i++) s[i]=s[i-1]+a[i];</pre>
   void mdf(int 1,int r,ll dt)
       int i;++r;
       ll j=dt*l;
       a[1] += dt; b[1] += j;
       while ((1+=1\&-1)<=n)
          a[1]+=dt;
          b[1]+=j;
       }
       if (r<=n)
          j=dt*r;
          a[r]-=dt;b[r]-=j;
          while ((r+=r\&-r)<=n)
              a[r]-=dt;
              b[r]-=j;
   11 presum(int x)
       11 r=a[x],rr=b[x];
       int y=x;
       while (x^=x\&-x)
          r+=a[x];
          rr+=b[x];
       return r*(y+1)-rr+s[y];
   }
   11 sum(int 1,int r)
       return presum(r)-presum(l-1);
};
```

#### 2.9 二维树状数组矩形加矩形求和

本质还是差分,只不过这次要维护  $d_{i,j}, d_{i,j}i, d_{i,j}i, d_{i,j}ij$ 。 $O(n^2) \sim O(q \log^2 n)$ , $O(n^2)$ 

```
struct bit2
   ll a[2050][2050],b[2050][2050],c[2050][2050],d[2050][2050];
   int n,m;
   private:
   void cha(ll a[][2050],int x,int y,int z)
       int i,j;
       for (i=x;i\leq n;i+=(i\&(-i))) for (j=y;j\leq m;j+=(j\&(-j))) a[i][j]+=z;
   11 he(int x,int y)
       if ((x<=0)||(y<=0)) return 0;</pre>
       int i,j;
       11 z=0, w=0;
       for (i=x;i;i==(i&(-i))) for (j=y;j;j==(j&(-j))) z+=a[i][j];
       z*=(x+1)*(y+1);
       w=0;
       for (i=x;i;i==(i\&(-i))) for (j=y;j;j==(j\&(-j))) w+=b[i][j];
       z=w*(y+1);
       w=0;
       for (i=x;i;i==(i\&(-i))) for (j=y;j;j==(j\&(-j))) w+=c[i][j];
       z = w*(x+1);
       for (i=x;i;i==(i\&(-i))) for (j=y;j;j==(j\&(-j))) z+=d[i][j];
       return z;
   }
   public:
   void init(int x,int y)
       n=x; m=y;
   void add(int u,int v,int x,int y,int z)//(x1,y1,x2,y2,dt)
       cha(a,u,v,z);
       cha(b,u,v,u*z);//小心乘爆
       cha(c,u,v,v*z);
       cha(d,u,v,u*v*z);
       ++x;++y;
       if (x \le n)
          cha(a,x,v,-z);
          cha(b,x,v,-z*x);
          cha(c,x,v,-z*v);

       }
       if (y<=m)
          cha(a,u,y,-z);
          cha(b,u,y,-z*u);
          cha(c,u,y,-z*y);
          cha(d,u,y,-z*u*y);
          if (x \le n)
           {
```

! 数据结构 18

```
cha(a,x,y,z);
    cha(b,x,y,z*x);
    cha(c,x,y,z*y);
    cha(d,x,y,z*x*y);
    }
}

ll sum(int u,int v,int x,int y)//(x1,y1,x2,y2)
{
    --u;--v;
    return (he(x,y)+he(u,v)-he(u,y)-he(x,v));
}
};
```

#### 2.10 带修莫队(功能:区间数有多少种不同的数字)

按照  $n^{\frac{2}{3}}$  分块,排序关键字是 l,r,t 所在的块(t 是版本号,每次修改都会增加一个版本),可以奇偶分块优化。

相比于传统莫队多了一个 modify。  $O(n^{\frac{5}{3}})$ , O(n)。

```
#include "bits/stdc++.h"
using namespace std;
typedef long long 11;
#define all(x) (x).begin(),(x).end()
const int N=1.4e5,M=1e6+2;
int a[N],ans[N],bel[N],cnt[M],sum,z,y,cur;
struct P
{
   int p,v;
};
struct Q
   int l,r,t,p;
   bool operator<(const Q &o) const</pre>
       if (bel[1]!=bel[0.1]) return bel[1] < bel[0.1];</pre>
       if (bel[r]!=bel[o.r]) return (bel[l]&1)^bel[r]<bel[o.r];</pre>
       return (bel[r]&1)?t<o.t:t>o.t;
   }
};
Q b[N];
P d[N];
void add(const int &x) {sum+=!(cnt[a[x]]++);}
void del(const int &x) {sum-=!(--cnt[a[x]]);}
void mdf(const int &x)
   auto &[p,v]=d[x];
   if (z<=p&&p<=y) del(p);</pre>
   swap(a[p],v);
   if (z<=p&&p<=y) add(p);</pre>
int main()
{
   ios::sync_with_stdio(0);cin.tie(0);
   int n,m,q1=0,q2=0,i,ksiz;
```

```
cin>>n>>m;
   for (i=1;i<=n;i++) cin>>a[i];
   for (i=1;i<=m;i++)</pre>
       char c;
       int 1,r;
       cin>>c>>l>>r;
       if (c=='Q') ++q1,b[q1]={1,r,q2,q1};
       else d[++q2]=\{1,r\};
   ksiz=max(1.0,round(cbrt((ll)n*n)));
   for (i=1;i<=n;i++) bel[i]=i/ksiz;</pre>
   sort(b+1,b+q1+1);
   z=b[1].1;y=z-1;cur=0;
   for (i=1;i<=q1;i++)</pre>
       auto [1,r,t,p]=b[i];
       while (z>1) add(--z);
       while (y<r) add(++y);</pre>
       while (z<1) del(z++);
       while (y>r) del(y--);
       while (cur<t) mdf(++cur);</pre>
       while (cur>t) mdf(cur--);
       ans[p]=sum;
   for (i=1;i<=q1;i++) cout<<ans[i]<<'\n';</pre>
}
```

#### 2.11 二次离线莫队

直接摘录题解,用途不大。

 $O(n\sqrt{n})$ , O(n).

珂朵莉给了你一个序列 a,每次查询给一个区间 [l,r],查询  $l \leq i < j \leq r$ ,且  $a_i \oplus a_j$  的二进制表示下有  $k \uparrow 1$  的二元组 (i,j) 的个数。 $\oplus$  是指按位异或。

二次离线莫队,通过扫描线,再次将更新答案的过程离线处理,降低时间复杂度。假设更新答案的复杂度为 O(k),它将莫队的复杂度从  $O(nk\sqrt{n})$  降到了  $O(nk+n\sqrt{n})$ ,大大简化了计算。设 x 对区间 [l,r] 的贡献为 f(x,[l,r]),我们考虑区间端点变化对答案的影响:以 [l..r] 变成 [l..(r+k)] 为例, $\forall x \in [r+1,r+k]$  求 f(x,[l,x-1])。我们可以进行差分: f(x,[l,x-1])=f(x,[1,x-1])-f(x,[1,l-1]),这样转化为了一个数对一个前缀的贡献。保存下来所有这样的询问,从左到右扫描数组计算就可以了。但是这样做,空间是  $O(n\sqrt{n})$  的,不太优秀,而且时间常数巨大。。这样的贡献分为两类:

1. 减号左边的贡献永远是一个前缀和它后面一个数的贡献。这可以预处理出来。2. 减号右边的贡献对于一次移动中所有的 x 来说,都是不变的。我们打标记的时候,可以只标记左右端点。

这样,减小时间常数的同时,空间降为了 O(n) 级别。是一个很优秀的算法了。处理前缀询问的时候,我们利用异或运算的交换律,即 a xor  $b=c \iff a$  xor c=b 开一个桶 t, t[i] 表示当前前缀中与 i 异或有 k 个数位为 1 的数有多少个。则每加入一个数 a[i],对于所有 popcount(x)=k 的x, t[a[i] xor  $x] \leftarrow t[a[i]$  xor x]+1 即可。

```
typedef long long ll;
const int N = 1e5 + 2, M = 1 << 14;
ll f[N], ans[N], ta[N];
int a[N], cnt[M], bel[N], pc[M], st[N];
int n, m, ksiz;
struct Q</pre>
```

```
{
   int z, y, wz;
   bool operator<(const Q &x) const { return (bel[z] < bel[x.z]) || (bel[z] == bel[x.z]) && ((y <</pre>
        x.y) && (bel[z] & 1) || (y > x.y) && (1 ^ bel[z] & 1)); }
};
Q mq(const int x, const int y, const int z)
   Qa;
   a.z = x; a.y = y; a.wz = z;

        na = 0; l = b[i][j].z; r = b[i][j].y;
        for (k = l; k <= r; k++) na += cnt[a[k]];
        if (b[i][j].wz > 0) ans[b[i][j].wz] += na; else ans[-b[i][j].wz] -= na;
}
}
for (i = 2; i <= m; i++) ans[i] += ans[i - 1];
for (i = 1; i <= m; i++) ta[q[i].wz] = ans[i];
for (i = 1; i <= m; i++) printf("%lld\n", ta[i]);
}</pre>
```

#### 2.12 回滚莫队

不删除的莫队,比如求 max。

做法: 块内询问暴力。对于 l 所在块相同的询问,按照 r 升序排序,并且将左指针固定在 l 所在块的最右侧。(由于块内询问暴力,这不会导致左指针更大)

回答每个询问的时候,先右端点右移到 r,然后左端点左移到 l。询问完成后,把左端点移回去。移回去的过程虽然涉及删除,但不需要维护答案变成什么了(因为在左端点左移之前已经求过了)。换句话说,相当于"撤销"而不是删除,完全可以记录移动过程中的所有变化来撤销。

 $O(n\sqrt{n})$ , O(n).

```
#include "bits/stdc++.h"
using namespace std;
const int N = 2e5 + 2;
int a[N], z[N], y[N], wz[N], b[N], d[N], bel[N], ans[N], st[N][2], pos[N][2];
void qs(int 1, int r)
{
   int i = 1, j = r, m = bel[z[1 + r >> 1]], mm = y[1 + r >> 1];
   while (i <= j)</pre>
       while ((bel[z[i]] < m) || (bel[z[i]] == m) && (y[i] < mm)) ++i;
       while ((bel[z[j]] > m) \mid | (bel[z[j]] == m) \&\& (y[j] > mm)) --j;
       if (i <= j)</pre>
       {
           swap(wz[i], wz[j]);
           swap(z[i], z[j]);
           swap(y[i++], y[j--]);
       }
   if (i < r) qs(i, r);</pre>
   if (1 < j) qs(1, j);</pre>
int main()
   ios::sync_with_stdio(false);
   cin.tie(0);
   cin >> n;
```

```
ksiz = sqrt(n);
for (i = 1; i <= n; i++) { cin >> a[i]; b[i] = a[i]; bel[i] = (i - 1) / ksiz + 1; }
sort(b + 1, b + n + 1);
d[gs = 1] = b[1];
for (i = 2; i <= n; i++) if (b[i] != b[i - 1]) d[++gs] = b[i];

```

#### 2.13 李超树

题意:插入线段,查询某个x的最大y(输出最小编号)

算法核心:修改时,线段树每个点只维护在中点取值最大的线段,中点取值较小的线段只会在至多一侧有用,递归下去插入,复杂度  $O(\log^2)$ 。查询时询问线段树上  $\log$  个点的线段中最大的。

```
struct Q

```

### 2.19 笛卡尔树的线性建树

p[1,2,...,n] 是原序列,c 表示子结点。 笛卡尔树满足堆性质(权值小于等于子结点权值),并且中序遍历是原序列。 O(n),O(n)。

```
int c[N][2],p[N],st[N];
int main()
{
    ios::sync_with_stdio(false);
    cin.tie(0);
    int i,n,tp=0;
    ll la=0,ra=0;
    cin>>n;
    for (i=1;i<=n;i++)
    {
        cin>>p[i];st[tp+1]=0;
        while ((tp)&&(p[st[tp]]>p[i])) --tp;
        c[c[st[tp]][1]=i][0]=st[tp+1];st[++tp]=i;
```

```
}
for (i=1;i<=n;i++) la^=(ll)i*(c[i][0]+1);
for (i=1;i<=n;i++) ra^=(ll)i*(c[i][1]+1);
cout<<la<<'u'<<ra<<endl;
}
</pre>
```

#### 2.20 扫描线

求矩形并的面积和周长(包括内周长)  $O((n+q)\log n)$ ,O(n+q)。

```
using T=11;
vector<T> fun(vector<tuple<T, T, T, T>> &a)
   vector<T> x;
   for (auto [x1, y1, x2, y2]:a)
       x.push_back(x1);
       x.push_back(x2);
   sort(all(x)); x.resize(unique(all(x))-x.begin());
   for (auto &[x1, y1, x2, y2]:a)
       x1=lower_bound(all(x), x1)-x.begin();
       x2=lower_bound(all(x), x2)-x.begin();
   return x;
}
struct sgt

```

#### 2.21 Segmenttree Beats!

核心是 P(tag)和 Q(info)的维护。线段树部分是套的模板,并非全都有用。

- 1. l, r, k: 对于所有的  $i \in [l, r]$ ,将  $A_i$  加上 k (k 可以为负数)。
- 2. l, r, v: 对于所有的  $i \in [l, r]$ , 将  $A_i$  变成  $min(A_i, v)$ 。
- 3. l, r:  $\Re \sum_{i=l}^{r} A_i$ .
- 4. l, r: 对于所有的  $i \in [l, r]$ ,求  $A_i$  的最大值。
- 5. l,r: 对于所有的  $i \in [l,r]$ ,求  $B_i$  的最大值。

其中  $B_i$  是  $A_i$  的历史最大值。

```

```

#### 2.28 表达式树

传入表达式,输出表达式树。

输入的第二个参数是全体括号以外的运算符,每个运算符要记录字符优先级和是否右结合。优 先级数字越大,越优先计算,且优先级必须为正整数。

输出的第一个参数是子结点数组,第二个参数是每个结点对应的字符,第三个参数是根。结点编号从 1 开始。

输出的表达式树满足每个结点对应一个字符。若包含数字串,则视为相邻数码之间加一个井号,表示"数码链接"这个运算符。你不需要,也不应该手动加入这个井号。

如果表达式非法,将返回根为 0。不允许一元运算符(负号),不允许省略乘号,不允许出现字母(除非字母是运算符)。

如果需要支持字母作为数字,修改所有包含 isdigit 的部分。

由于存在"数码链接",在 dfs 树的时候最好记录一下子树大小,便于链接时计算(你不能在链接时直接看右子树的数字大小,因为有可能有前导 0)。

```
struct Q
{
   char ch;
   int prec;
   bool right;
};
tuple<vector<array<int, 2>>, vector<char>, int> parse_expr(string s, vector<Q> op) {
   static int idx[128];
   int maxp = 0, pos = 0, n, err = 0, i;
       string t;
       for (char c : s)
          if (t.size() && isdigit(t.back()) && isdigit(c)) t += '#';
          t += c;
       swap(s, t);
       n = s.size();
   for (i = 0; i < op.size(); ++i)</pre>
```

```

```

#### 2.29 区间排序区间复合

时空  $O((n+m)\log V)$ ,其中 V 是排序关键字的值域,要求排序关键字唯一。实际效率较低, $10^5$  要  $1.2\mathrm{s}$ 。

构造函数传入排序关键字与信息,以及排序关键字的值域范围。与其他板子不同的是,所有区间都是左闭右开的,下标从 0 开始。

```
template < class T, class info > struct range_sort

       }
      return r;
   }
}
using Prime::pr,Prime::phi,Prime::getw,Prime::getphi;
using Prime::mu,Prime::init_prime;
ui ksm(ll x,ui y,ui p)
{
   x=x^p+(x>=p)*p;
   ll r=1;
   while (y)
       if (y&1)
          if ((r*=x)>=p) r=r%p+p; else r%=p;
      if ((x*=x)>=p) x=x%p+p; else x%=p;
      y>>=1;
   return r;
struct Q
   vector<ui> p;
   Q(const ui &P)
```

```
p.push_back(P);
       while (p.back()>1) p.push_back(getphi(p.back()));
   }
   ui operator()(ll a,ll b)
       if (!a) return (1^b&1)%p[0];
       ui r=1;
       int i=min(b,(ll)p.size());
       while ((--i)>=0) r=ksm(a,r,p[i]);
       return r%p[0];
   }
};
int main()
{
   ios::sync_with_stdio(0);cin.tie(0);
   cout<<setiosflags(ios::fixed)<<setprecision(15);</pre>
   int n,i;
   init_prime();
   int T;
   cin>>T;
   while (T--)
       ui a,b,c;
       cin>>a>>b>>c;
       cout << Q(c)(a,b) << ' n';
   }
}
```

### $3.7 \quad \text{exgcd}$

```
O(\log p),O(\log p)。
递归版:
```

```
int exgcd(int a,int b,int c)//ax+by=c,return x
{
    if (a==0) return c/b;
    return (c-(ll)b*exgcd(b%a,a,c))/a%b;
}
```

#### 递推重构版:

```
pair<11,11> exgcd(11 a,11 b,11 c)//ax+by=c, {-1,-1} 无解, b=0 返回 {c/a,0}, 否则返回最小非负 x {
    assert(a||b);
    if (!b) return {c/a,0};
    if (a<0) a=-a,b=-b,c=-c;
    ll d=gcd(a,b);
    if (c%d) return {-1,-1};
    ll x=1,x1=0,p=a,q=b,k;
    b=abs(b);
    while (b) {
        k=a/b;
        x-=k*x1;a==k*b;
        swap(x,x1);
        swap(a,b);
    }
```

```
b=abs(q/d);
    x=(c/d)%b*(x%b)%b;
    if (x<0) x+=b;
    return {x, (ll)((c-(lll)p*x)/q)};
}
ll fun(ll a, ll b, ll p)//ax=b(mod p)
{
    return exgcd(a, -p, b).first%p;
}</pre>
```

### $3.8 \quad exCRT$

实现了一个类 Q,表示一条方程,支持合并。

```
namespace CRT
   typedef long long 11;
   pair<ll,ll> exgcd(ll a,ll b,ll c)
       assert(a||b);
       if (!b) return {c/a,0};
       11 d=gcd(a,b);
       if (c%d) return {-1,-1};
       ll x=1,x1=0,p=a,q=b,k;
       b=abs(b);
       while (b)
          k=a/b;
          x==k*x1;a==k*b;
          swap(x,x1);
          swap(a,b);
       }
       b=abs(q/d);
       x=x*(c/d)\%b;
       if (x<0) x+=b;
       return \{x,(c-p*x)/q\};
   }
   struct Q
       11 p,r;//0<=r<p</pre>
       Q operator+(const Q &o) const
          if (p==0||o.p==0) return {0,0};
          auto [x,y]=exgcd(p,-o.p,r-o.r);
          if (x==-1&&y==-1) return {0,0};
          11 q=lcm(p,o.p);
          return {q,((r-x*p)%q+q)%q};
       }
   };
using CRT::Q;
```

#### 3.9 exBSGS

 $O(\sqrt{n})$ 。哈希表 ht 可以用 map 代替。

```
namespace BSGS
   typedef unsigned int ui;
   typedef unsigned long long 11;
   template<int N, class T, class TT> struct ht//个数, 定义域, 值域
      const static int p=1e6+7,M=p+2;
      TT a[N];

### 3.11 杜教筛

```
求 \varphi(n) 的前缀和。
核心: 构造 g 满足 h(n) = \sum_{d \mid n} f(d) g(\frac{n}{d}) 容易计算,则有 \sum_{i=1}^n h(i) = \sum_{i=1}^n g(i) \sum_{j=1}^{\lfloor n/i \rfloor} f(j),故 g(1) \sum_{j=1}^n f(j) = \sum_{i=1}^n h(i) - \sum_{i=2}^n g(i) \sum_{j=1}^{\lfloor n/i \rfloor} f(j),则 f 前缀和可以递归求解。
```

```
pr[cnt++]=i;
              phi[i]=i-1;
           }
          for (j=0;i*pr[j]<N;j++)</pre>
              if (i%pr[j]==0)
                  phi[i*pr[j]]=phi[i]*pr[j];
              phi[i*pr[j]]=phi[i]*(pr[j]-1);
           if ((phi[i]+=phi[i-1])>=p) phi[i]-=p;
       }

   return r;
```

#### 3.28 NTT

一种较快的 NTT (尤其是对于卷积以外的用途),但不推荐在不熟悉的情况下直接使用。一般的卷积可以参照字符串部分通配符的字符串匹配,其余的用途可以参照其他板子。

如果确实需要卡常,建议先抄写需要的函数,并递归地找到需要补的内容。

注意事项: 所有 11 为无符号。始终保证数组大小为  $2^n$ ,不应当使用 resize 而应该使用取模来调整长度。三种卷积对应的运算符见注释。

需要特别小心其长度的变化,注意不要越界。如果修改模数,dft 和 hf\_dft 处有一个参数也要修改。

常见函数如下(带 new 的基本上都是较快但较长的):

卷积 operator\*, 循环卷积 operator&, 差卷积 operator^, 求逆 operator~/ (包含一个较短版,被注释了),分治 cdq,对数 ln,指数 exp,exp\_cdq,exp\_new,开方 sqrt,sqrt\_new,幂函数 pow(Q,11),pow(Q,string),pow2(Q,11),pow(Q,11,Q),整除与取模 div,mod,div\_mod,线性递推 recurrent,recurrent\_new,recurrent\_interval,连乘 prod,prod\_new,

多点求值 evaluation, evaluation\_new,阶乘 factorial,快速插值 interpolation,复合(逆)comp,comp\_inv,多项式平移 shift,区间点值平移 shift,Z 变换 Z\_transform,贝尔数([n] 划分等价类方案数)Bell,斯特林数 S1\_row,S1\_column,S2\_row,S2\_column,signed\_S1\_row,伯努利数 Bernoulli,划分数 Partition,最大公因式 gcd,求根 root,模多项式意义的逆 inverse。

```
#include <optional>
namespace NTT

# 3.32 万能欧几里得/min of mod of linear

原理:考虑紧贴着斜线的折线的答案。每个 nd 表示的是一段折线,你需要实现 operator+来 计算出拼接两个折线之后的答案。除此以外的原理不必了解。

你需要传入的 dx 和 dy 表示向上和向右的折线的答案(也就是边界)。

```
struct nd
{
    11 x, y, sy;
    nd operator+(const nd &o) const
    {
        return {x + o.x, y + o.y, sy + o.sy + y * o.x};
    }
};
nd ksm(nd a, int k)
{
    nd res{ };
    while (k)
    {
        if (k & 1) res = res + a;
            a = a + a; k >>= 1;
    }
    return res;
}
nd sol(int a, int b, int m, int n, nd dx, nd dy)//[0,n] (ax+b)/m 0<=b<m
{</pre>
```

```
if (!n) return { };
   if (a \ge m) return sol(a \% m, b, m, n, ksm(dy, a / m) + dx, dy);
   int c = ((11)n * a + b) / m;
   if (!c) return ksm(dx, n);
   int cnt = n - ((11)m * c - b - 1) / a;
   return ksm(dx, (m - b - 1) / a) + dy + sol(m, (m - b - 1) % a, a, c - 1, dy, dx) + ksm(dx, cnt
       );
11 sum_of_floor_of_linear(int a, int b, int m, int n)//[0,n] sum((ax+b)/m)
   nd dx = \{1, 0, 0\}, dy = \{0, 1, 0\};
   int nb = (b \% m + m) \% m;
   return sol(a, nb, m, n, dx, dy).sy + (ll)(b - nb) / m * (n + 1);
}
int min_of_mod_of_linear(int a, int b, int p, int n)//[0,n] min((ax+b) mod p)
   ll s = sum_of_floor_of_linear(a, b, p, n);
   int 1 = 0, r = p - 1, mid;
   while (1 < r)
       mid = (1 + r + 1) / 2;
       if (sum_of_floor_of_linear(a, b - mid, p, n) >= s) l = mid;
       else r = mid - 1;
   return 1;
```

### 3.33 高斯整数类

圆上整点的基础。

```
ll roundiv(ll x,ll y)
{
   return x \ge 0?(x+y/2)/y:(x-y/2)/y;
struct Q
{
   11 x,y;
   Q operator~() const { return {x,-y}; }

```

# 4 字符串

## 4.1 字典树(trie 树)

```
struct trie
   const static int N=3e6+2, M=62;
   int c[N][M], sz[N];//sz 维护有多少个以当前字符串为前缀的字符串。
   int cnt;
   void insert(string s)
      int u=0;
      ++sz[u];
      for (char ch:s)
         assert(ch>=0&&ch<M);</pre>
         int &v=c[u][ch];
         if (!v) v=++cnt;
         u=v;
         ++sz[u];
      //此时 u 是字符串结束位置。你可以在此存储结点信息。
   int match(string s)//返回字符串结束位置。可能为 0。
   {
      int u=0;
      for (char ch:s)
         assert(ch>=0&&ch<M);
         u=c[u][ch];
         if (!u) return 0;
      }
      return u;
   }
   void clear()
      memset(c, 0, (cnt+1)*sizeof c[0]);
      memset(sz, 0, (cnt+1)*sizeof sz[0]);
      cnt=0;
   }
} s;
```

## 4.2 AC 自动机

注意 AC 自动机与 trie 不同的地方在于, 根必须是 0。

题意: 给你一个文本串 S 和 n 个模式串  $T_{1\sim n}$ ,请你分别求出每个模式串  $T_i$  在 S 中出现的次数。

```
struct AC
{
   const static int N=3e6+2, M=26;
   int c[N][M], sz[N], pos[N], f[N], app[N];//sz 维护有多少个以当前字符串为前缀的字符串。
   int cnt=0, id=0;
   vector<int> q;
   void insert(string s)
   {
```

```
int u=0;
       ++sz[u];
       for (char ch:s)
          assert(ch>=0&&ch<M);
          int &v=c[u][ch];
          if (!v) v=++cnt;
          u=v;
          ++sz[u];
      pos[id++]=u;
       //此时 u 是字符串结束位置。你可以在此存储结点信息。
   vector<int> match(string s)//返回答案。复杂度 O(结点数)
       int u=0, i;
      for (char ch:s)
          assert(ch>=0&&ch<M);
          u=c[u][ch];
          ++app[u];
      for (int u:q) app[f[u]]+=app[u];
       vector<int> r(id);
       for (i=0; i<id; i++) r[i]=app[pos[i]];</pre>
      memset(app, 0, (cnt+1)*sizeof app[0]);
      return r;
   void clear()
   {
       memset(c, 0, (cnt+1)*sizeof c[0]);

string t;
cin>>t;
for (char &c:t) c-='a';
auto res=s.match(t);
for (int x:res) cout<<x<<'\n';
}</pre>
```

### 4.3 hash

在调试时,可以把 base 设置为 10 的幂方便输出。可能建议把第一个模数也设置为 1,但未测试是否有奇怪的问题。但要注意,此时不应当使用接近 10 的幂次的模数。

```
O(n), O(n).
```

双模数版本:注意使用的是无符号数,效率比 int128 高,但不卡常建议抄 int128 版本。

特别注意这里 m 数组预处理的不是幂次,而是幂次的相反数。如果有复杂的变换需要建议用 int128 版本。

其返回值是两个32位数拼接而成的,要改动比较麻烦。

```
namespace sh
   typedef unsigned int ui;
   typedef unsigned long long 11;
   const int N=1e6+5;
   const 11 p1=2'034'452'107, \( \text{p2=2'013'074'419} \);
   struct pa
       ll v1, v2;
       pa(11 v=0):v1(v), v2(v) { }
       pa(ll v1, ll v2):v1(v1), v2(v2) { }
       pa operator*(const pa &o) const { return {v1*o.v1%p1, v2*o.v2%p2}; }
   };
   pa fma(const pa &a, const pa &b, const pa &c) { return {(a.v1*b.v1+c.v1)%p1, (a.v2*b.v2+c.v2)%
   const pa b=\{137, 149\}, inv=\{1'603'801'661, 1'024'053'074\};
   pa m[N];
   void init()
       m[0] = \{p1-1, p2-1\};
       for (int i=1; i<N; i++) m[i]=m[i-1]*b;</pre>
   int i=(init(), 0);
   struct str
   {
       int n;
       template<class T> str(const vector<T> &s):n(s.size()), a(n+1)
       {
```

```
for (i=0; i<n; i++) a[i+1]=fma(a[i], b, s[i]);</pre>
       }
       template<class T> str(const basic_string<T> &s):n(s.size()), a(n+1)//直接去掉模板换成
           string 也可以
          for (i=0; i<n; i++) a[i+1]=fma(a[i], b, s[i]);</pre>
       }
       ll getv(int l, int r)//[l,r)
          auto [x, y]=fma(a[1], m[r-1], a[r]);
          return x<<32|y;</pre>
       }
   };
}
using sh::str;
int main()
{
   ios::sync_with_stdio(0); cin.tie(0);
   int T; cin>>T;
   set<ull> s;
   while (T--)
       string t;
       cin>>t;
       s.insert(str(t).getv(0, t.size()));
   cout<<s.size()<<endl;</pre>
}
```

## \_\_int128 版本:

```
namespace sh
{
   typedef __uint128_t 111;
   const int N=1e6+5;
   const 111 p=1'80'143'985'094'819'841, b=137;
   lll m[N];
   void init()
       m[0]=1;
       for (int i=1; i<N; i++) m[i]=m[i-1]*b%p;</pre>
   int i=(init(), 0);
   struct str
   {
       int n;
       vector<lll> a;
       template<class T> str(const vector<T> &s):n(s.size()), a(n+1)
          for (i=0; i<n; i++) a[i+1]=(a[i]*b+s[i])%p;</pre>
       template<class T> str(const basic_string<T> &s):n(s.size()), a(n+1)//直接去掉模板换成
           string 也可以
       {
          for (i=0; i<n; i++) a[i+1]=(a[i]*b+s[i])%p;</pre>
       lll getv(int l, int r)//[l,r)
       {
```

```
return (a[r]+(p-a[1])*m[r-1])%p;
};
};
using sh::str;
```

### 4.4 KMP

O(n), O(n).

```

       dfs(1);
       return ans-n;
   }
};
```

# 4.11 Z 函数

表示每个后缀和母串的 lcp。

```
vector<int> Z(const string &s)
{
   int n=s.size(),i,l,r;
   vector<int> z(n);
   z[0]=n;
   for (i=1,l=r=0; i<n; i++)
   {
      if (i<=r&&z[i-1]<r-i+1) z[i]=z[i-1];
      else
      {
            z[i]=max(0,r-i+1);
            while (i+z[i]<n&&s[i+z[i]]==s[z[i]]) ++z[i];
      }
      if (i+z[i]-1>r) l=i,r=i+z[i]-1;
   }
   return z;
}
```

# 4.12 最小表示法

找到一个串的循环同构串中字典序最小的那个,将这个串直接变过去。常见应用:环哈希(基环树哈希)。

如果只需要找到起点下标,在 rotate 前返回  $\min\{i,j\}$  即可。

O(n), O(1)

```
template<class T> void min_order(vector<T>& a)
   int n = a.size(), i, j, k;
   a.resize(n * 2);
   for (i = 0;i < n;i++) a[i + n] = a[i];</pre>
   i = k = 0; j = 1;
   while (i < n \&\& j < n \&\& k < n)
       T x = a[i + k], y = a[j + k];
       if (x == y) ++k; else
           (x > y ? i : j) += k + 1;
          j += (i == j);
          k = 0;
       }
   a.resize(n);
   //[min(i,j),n)+[0,min(i,j))
   rotate(a.begin(), min(i, j) + all(a));
}
```

# 4.13 带通配符的字符串匹配

原理: 匹配等价于  $\sum (f_i - g_i)^2 = 0$ 。带通配符等价于  $\sum f_i g_i (f_i - g_i)^2 = 0$ ,展开即可。 这里也是较为推荐的 NTT 版本,直接实现任意长度的多项式相乘,便于一般情况的运用。不需要提前做任何 init。

```
namespace NTT
   typedef unsigned ui;
   typedef unsigned long long 11;
   const int N=1<<22;</pre>
   const ui p=998244353, g=3;
   inline ui ksm(ui x, ui y)
       ui ans=1;
       while (y)
           if (y&1) ans=1llu*ans*x%p;
           y>>=1; x=1llu*x*x%p;
       return ans;
   ui r[N], w[N];
   void ntt(vector<ui> &a)
       int n=a.size(), i, j, k;
       for (i=0; i<n; i++) if (i<r[i]) swap(a[i], a[r[i]]);</pre>
       for (k=1; k<n; k<<=1)</pre>
```

```
{
           for (i=0; i<n; i+=k<<1)</pre>
              for (j=0; j<k; j++)</pre>
                  ui x=a[i+j], y=1llu*a[i+j+k]*w[j+k]%p;
                  a[i+j]=(x+y)%p; a[i+j+k]=(x+p-y)%p;
              }
           }
       }
   vector<ui> mul(vector <ui> a, vector <ui> b)
       if (a.size()==0||b.size()==0) return { };
       int m=a.size()+b.size()-1;
       int n=1<<__lg(m*2-1);</pre>
       int i, j, base=_{-}lg(n)-1;
       ui inv=ksm(n, p-2);
       for (i=1; i<n; i++) r[i]=r[i>>1]>>1|(i&1)<<base;</pre>
       for (j=1; j<n; j<<=1)</pre>
           ui wn=ksm(3, (p-1)/(j << 1));

   return ans;
}
```

# 5.1 最小生成树相关

### 5.1.1 切比雪夫距离最小生成树

原理: 先转曼哈顿距离,再用曼哈顿的板子。 $O(n \log n)$ , O(n)。

```
const int N=3e5+2,M=N<<2;</pre>
struct P
{
   int u,v,w;
   P(int a=0,int b=0,int c=0):u(a),v(b),w(c){}
   bool operator<(const P &o) const {return w<o.w;}</pre>
};
struct Q
{
   int x,y,id;
   Q(int a=0, int b=0, int c=0):x(a),y(b),id(c){}
   bool operator<(const Q &o) const {return x!=o.x?x>o.x:y>o.y;}
};
ll ans;
P lb[M];
Q a[N],b[N];
int f[N],c[N];
int n,m,i,x,y;
struct bit
   int a[N],pos[N],n;
   void init(int &nn)
       memset(a+1,0x7f,(n=nn)*sizeof a[0]);
       memset(pos+1,0,n*sizeof pos[0]);
   void mdf(int x,const int y,const int z)
       if (a[x]>y) a[x]=y,pos[x]=z;
       while (x-=x\&-x) if (a[x]>y) a[x]=y,pos[x]=z;
   int sum(int x)
       int r=a[x],rr=pos[x];
       while ((x+=x\&-x)\le n) if (a[x]\le r) r=a[x], rr=pos[x];
       return rr;
   }
};
bit s;
void cal()
   int i,x,y;
   s.init(n);
   memcpy(b+1,a+1,sizeof(Q)*n);
   sort(a+1,a+n+1);
   for (i=1;i<=n;i++) c[i]=a[i].y-a[i].x;</pre>
   sort(c+1,c+n+1);
   for (i=1;i<=n;i++)</pre>
```

```
{
    if (x=s.sum(y=lower_bound(c+1,c+n+1,a[i].y-a[i].x)-c))
        lb[++m]=P(a[x].id,a[i].id,a[x].x+a[x].y-a[i].x-a[i].y);//谨防 int 場
        s.mdf(y,a[i].y+a[i].x,i);
    }
    memcpy(a+1,b+1,sizeof(Q)*n);
}
int getf(int x) {return f[x]==x?x:f[x]=getf(f[x]);}
int main()
{
    cin>n;
    for (i=1;i<=n;i++) {cin>>a[f[i]=a[i].id=i].x>>a[i].y;
        swap(a[i].x,a[i].y);a[i]=Q(a[i].x+a[i].y,a[i].x-a[i].y,i);}
    cal();for (i=1;i<=n;i++) swap(a[i].x,a[i].y);
    cal();for (i=1;i<=n;i++) a[i].y-a[i].y;
    cal();for (i=1;i<=n;i++) swap(a[i].x,a[i].y);

    for (i=1;i<=m;i++) if ((x=getf(lb[i].u))!=(y=getf(lb[i].v))) f[x]=y,ans+=lb[i].w;
    cout<<ans/2<<endl;
}
```

#### 5.1.2 最小乘积生成树

题意:每条边有两个属性  $x_i, y_i$ ,你需要最小化  $(\sum x_i)(\sum y_i)$ 。 你需要实现的是 sol1,即按照 val 为权值的答案。 $val_i$  是根据  $x_i, y_i$  计算的。

```
#include "bits/stdc++.h"
using namespace std;
typedef long long 11;
const int N = 202, M = 10002;
struct P
   int x, y;
   P(int a = 0, int b = 0) : x(a), y(b) { }
   bool operator<(const P &o) const { return (11)x * y < (11)o.x * o.y || (11)x * y == (11)o.x *
       o.y && x < o.x; }
};
struct Q
{
   int u, v, x, y, val;
   bool operator<(const Q &o) const { return val < o.val; }</pre>
};
P \text{ ans} = P(1e9, 1e9), 1, r;
Q a[M];
int f[N];
int n, m, i;
int getf(int x)
   if (f[x] == x) return x;
   return f[x] = getf(f[x]);
P sol1()
   P r = P(0, 0);
   for (i = 1; i <= n; i++) f[i] = i;</pre>
   sort(a + 1, a + m + 1);
   for (i = 1; i <= m; i++) if (getf(a[i].u) != getf(a[i].v))</pre>
```

```
f[f[a[i].u]] = f[a[i].v];
       r.x += a[i].x, r.y += a[i].y;
   return r;
void sol2(P 1, P r)
{
   for (i = 1; i \le m; i++) a[i].val = (r.x - l.x) * a[i].y + (l.y - r.y) * a[i].x;
   P np = sol1();
   ans = min(ans, np);
   if ((11)(r.x - 1.x) * (np.y - 1.y) - (11)(r.y - 1.y) * (np.x - 1.x) >= 0) return;
   sol2(1, np); sol2(np, r);
}
int main()
   cin >> n >> m;
   for (i = 1; i <= m; i++) cin >> a[i].u >> a[i].v >> a[i].x >> a[i].y, ++a[i].u, ++a[i].v;
   for (i = 1; i <= m; i++) a[i].val = a[i].x; l = sol1();</pre>
   for (i = 1; i <= m; i++) a[i].val = a[i].y; r = sol1();</pre>
   ans = min(ans, min(1, r)); sol2(1, r);
   cout<<ans.x<<'u'<<ans.y<<endl;</pre>
}
```

#### 5.1.3 最小斯坦纳树

题意: 让给定点集连通的最小生成树(不要求全图连通) $O(3^k n + 2^k m \log m)$ 。

```
const int N = 102, M = 1002, K = 1024;
typedef long long 11;
typedef pair<ll, int> pa;
priority_queue<pa, vector<pa>, greater<pa> > heap;
pa cr;
11 f[K][N], inf;
int lj[M], len[M], nxt[M], fir[N];
int n, m, q, i, j, k, x, y, z, bs, c;
void add()
   lj[++bs] = y;
   len[bs] = z;
   nxt[bs] = fir[x];
   fir[x] = bs;
   lj[++bs] = x;
   len[bs] = z;
   nxt[bs] = fir[y];
   fir[y] = bs;
void dijk(int s)
{
   int i;
   while (!heap.empty())
       x = heap.top().second; heap.pop();
       for (i = fir[x]; i; i = nxt[i]) if (f[s][lj[i]] > f[s][x] + len[i])
          cr.first = f[s][cr.second = lj[i]] = f[s][x] + len[i];
```

```
heap.push(cr);
      while ((!heap.empty()) && (heap.top().first != f[s][heap.top().second])) heap.pop();
   }
int main()
   memset(f, 0x3f, sizeof(f)); inf = f[0][0];
   cin >> n >> m >> q;
   while (m--)
      cin >> x >> y >> z;
      add();
   }
   for (i = 1; i <= q; i++)</pre>
      cin >> x;
      f[1 << i - 1][x] = 0;
   }
   q = (1 << q) - 1;
   for (i = 1; i <= q; i++)</pre>
      for (k = 1; k \le n; k++)
          for (j = i \& (i - 1); j; j = i \& (j - 1)) f[i][k] = min(f[i][k], f[j][k] + f[i ^ j][k])
          dijk(i);
   for (i = 1; i <= n; i++) inf = min(inf, f[q][i]);</pre>
   cout << inf << endl;</pre>
}
```

# 5.2 最短路相关

### 5.2.1 全源最短路与判负环

使用 floyd 实现全源最短路与判负环。注意边权较大时可能需要考虑 int128.

```
#include "bits/stdc++.h"
using namespace std;
typedef long long ll;
typedef pair<int,int> pa;
typedef tuple<int,int,int> tp;
const int N=152;
const ll inf=5e8;
ll dis[N][N],d[N][N];
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    while (1)
    {
        int n,m,q,i,j,k;
        cin>>n>>m>>q;
        if (tp(n,m,q)==tp(0,0,0)) return 0;
        for (i=0;i<n;i++) fill_n(dis[i],n,inf*inf);</pre>
```

```
for (i=0;i<n;i++) dis[i][i]=0;</pre>
                                                         while (m--)
                                                                                     int u,v,w;
                                                                                     cin>>u>>v>>w;
                                                                                     dis[u][v]=min(dis[u][v],(11)w);

                                                                                     <<"-Infinity\n"; else cout<<d[u][v]<<'\n';
                                                         }
                                                         cout<<'\n';</pre>
                            }
}
```

### 5.2.2 Dijkstra/SPFA/Johnson

Johnson 不适用于图中存在负环的情况,因为负环不一定是可以经过的。  $O(nm \log m)$ , O(n+m)。

```
vector<ll> spfa(const vector<vector<pair<int, ll>>> &e, int s)
{
   int n=e.size(), i;
   assert(n);
   queue<int> q;
   vector<int> len(n), ed(n);
   vector<ll> dis(n, inf);
   q.push(s); dis[s]=0;
   while (q.size())
       int u=q.front(); q.pop();
       ed[u]=0;
       for (auto [v, w]:e[u]) if (cmin(dis[v], dis[u]+w))
          len[v]=len[u]+1;
          if (len[v]>n) return { };
          if (!ed[v])
              ed[v]=1;
              q.push(v);
          }
       }
   }
   return dis;
vector<ll> spfa(const vector<vector<pair<int, ll>>> &e)
   int n=e.size(), i;
   assert(n);
```

```
queue<int> q;
   vector<int> len(n), ed(n, 1);
   vector<ll> dis(n);
   for (i=0; i<n; i++) q.push(i);</pre>
   while (q.size())
       int u=q.front(); q.pop();
       ed[u]=0;
       for (auto [v, w]:e[u]) if (cmin(dis[v], dis[u]+w))
          len[v]=len[u]+1;
          if (len[v]>n) return { };
          if (!ed[v])
              ed[v]=1;
              q.push(v);
          }
       }
   }
   return dis;
vector<11> dijk(const vector<vector<pair<int, 11>>> &e, int s)
   int n=e.size();
   using pa=pair<ll, int>;
   vector<ll> d(n, inf);
   vector<int> ed(n);
   priority_queue<pa, vector<pa>, greater<pa>> q;
   d[s]=0; q.push({0, s});
   while (q.size())
       int u=q.top().second; q.pop();
       ed[u]=1;
       for (auto [v, w]:e[u]) if (cmin(d[v], d[u]+w)) q.push({d[v], v});
       while (q.size()&&ed[q.top().second]) q.pop();
   }
   return d;
}
vector<vector<ll>>> dijk(const vector<vector<pair<int, ll>>> &e)
   vector<vector<ll>> r;
   for (int i=0; i<e.size(); i++) r.push_back(dijk(e, i));</pre>
   return r;
vector<vector<ll>> john(vector<vector<pair<int, ll>>> e)
   int n=e.size(), i, j;
   assert(n);
   auto h=spfa(e);
   if (!h.size()) return { };
   for (i=0; i<n; i++) for (auto &[v, w]:e[i]) w+=h[i]-h[v];</pre>
   auto r=dijk(e);
   for (i=0; i<n; i++) for (j=0; j<n; j++) if (r[i][j]!=inf) r[i][j]-=h[i]-h[j];
   return r;
```

#### 5.2.3 无向图最小环

原理: floyd 外层循环本质是计算只经过  $\leq k$  的点的最短路。因此枚举环上标号最大的,在做这一轮转移之前正好是不经过它的最短路。

```
O(n^3), O(n^2)_{\circ}
```

#### 5.2.4 输出负环

```
#include "bits/stdc++.h"
using namespace std;
const int N=34;
struct Q
   int v,w,c;
   Q(){}
   Q(int x, int y, int z): v(x), w(y), c(z){}
};
vector<Q> lj[N];
int dis[N],cnt[N],pt[N],S;
Q pre[N],st[N];
int n,m,ans,tp;
bool ed[N];
int main()
{
   freopen("arbitrage.in", "r", stdin);
   freopen("arbitrage.out", "w", stdout);
   ios::sync_with_stdio(0);cin.tie(0);
   cin>>n>>m;
   while (m--)
       int x,y,z,w;
       cin>>x>>y>>z>>w;
       lj[x].emplace_back(y,w,z);
       lj[y].emplace_back(x,0,-z);
```

```
for (int i=1;i<=n;i++) lj[0].emplace_back(i,1,0);</pre>
   while (1)
       memset(dis,-0x3f,sizeof dis);dis[0]=0;
       for (int i=0;i<=n;i++) ed[i]=cnt[i]=0;S=-1;</pre>
       queue<int> q;q.push(0);
       while (!q.empty())
           int u=q.front();q.pop();ed[u]=0;
           for (auto &[v,w,c]:lj[u]) if (w&&dis[v]<dis[u]+c)</pre>
              dis[v]=dis[u]+c;pre[v]=Q(u,w,c);
              if (!ed[v])
                  if (++cnt[v]>n+1) {S=v;goto aa;}
                  ed[v]=1;q.push(v);
              }
          }
       }
       aa:;
       if (S==-1) break;
           static bool ed[N];
           memset(ed,0,sizeof ed);
           while (!ed[S]) ed[S]=1,S=pre[S].v;
       st[tp=1]=pre[S];pt[1]=S;
       int x=pre[S].v;
       while (x!=S)
           st[++tp]=pre[x];pt[tp]=x;
           x=pre[x].v;
           assert(tp<=n+5);</pre>
       }
       int fl=1e9;
       for (int j=1;j<=tp;j++) fl=min(fl,st[j].w);</pre>
       assert(f1);
       for (int j=1;j<=tp;j++)</pre>
           ans+=fl*st[j].c;
           int nn=0;
           for (auto &[v,w,c]:lj[st[j].v]) if (v==pt[j]&&st[j].c==c&&st[j].w==w) {++nn;w-=fl;break
           for (auto &[v,w,c]:lj[pt[j]]) if (v==st[j].v&&st[j].c+c==0) {++nn;w+=fl;break;}assert(
               nn==2);
       }
   }
   cout<<ans<<endl;</pre>
}
```

# 5.3 二分图与网络流建图

以下约定,若为二分图则 n, m 表示两侧点数,否则仅 n 表示全图点数。

### 5.3.1 二分图边染色

留坑待填。

结论:  $\Delta(G) \leq \chi'(G) \leq \Delta(G) + 1$ ,二分图时  $\chi'(G) = \Delta(G)$ 。 $\Delta(G)$  为图的最大度。

#### 5.3.2 二分图最小点集覆盖

ans = maxmatch, 方案如下。

```
#include "bits/stdc++.h"
using namespace std;
const int N=5e3+2;
vector<int> e[N];
int ed[N],lk[N],kl[N],flg[N],now;
bool dfs(int u)
   for (int v:e[u]) if (ed[v]!=now)
       ed[v]=now;
       if (!lk[v]||dfs(lk[v])) return lk[v]=u;
   return 0;
void dfs2(int u)
   for (int v:e[u]) if (!flg[v]) flg[v]=1,dfs2(lk[v]);
int main()
   int n,m,i,r=0;
   cin>>n>>m;
   while (m--)
       int u,v;
       cin>>u>>v;
       e[u].push_back(v);
   for (i=1;i<=n;i++) dfs(now=i);</pre>
   for (i=1;i<=n;i++) kl[lk[i]]=i;</pre>
   for (i=1;i<=n;i++) if (!kl[i]) dfs2(i);</pre>
   vector<int> A[2];
   for (i=1;i<=n;i++) if (lk[i])</pre>
       if (flg[i]) A[1].push_back(i); else A[0].push_back(lk[i]);
   for (int j=0;j<2;j++)</pre>
       cout<<A[j].size();</pre>
       for (int x:A[j]) cout<<'u'<<x;cout<<'\n';</pre>
   }
}
```

#### 5.3.3 二分图最大独立集

ans = n + m - maxmatch, 方案是最小点集覆盖的补集。

### 5.3.4 二分图最小边覆盖

ans = n + m - maxmatch,方案是最大匹配加随便一些边(用于覆盖失配点)。无解当且仅当有孤立点,算法会视为单选孤立点(无边)。这个定理对一般图也成立。

### 5.3.5 有向无环图最小不相交链覆盖

ans = n - maxmatch,其中二分图建图方法是拆入点和出点(实现时直接跑一次二分图就行,不用额外处理),注意**不**需要传递闭包。方案如下。

```
#include "bits/stdc++.h"
using namespace std;
const int N=152;
vector<int> e[N];
int lk[N],kl[N],ed[N],now;
bool dfs(int u)
{
   for (int v:e[u]) if (ed[v]!=now)
      ed[v]=now;
      if (!lk[v]||dfs(lk[v])) return lk[v]=u;
   return 0;
int main()
{
   int n,m,i;
   ios::sync_with_stdio(0);cin.tie(0);
   cin>>n>>m;
   while (m--)
      int u,v;
      cin>>u>>v;
      e[u].push_back(v);
   }
   int r=0;
   for (i=1;i<=n;i++) r+=dfs(now=i);</pre>
   for (i=1;i<=n;i++) kl[lk[i]]=i;</pre>
   for (i=1;i<=n;i++) if (ed[i]!=-1&&!lk[i])</pre>
      vector<int> ans;
      int u=i;
      while (u)
         ed[u] = -1;
         ans.push_back(u);
         u=kl[u];
      }
      }
   cout<<n-r<<endl;</pre>
```

### 5.3.6 有向无环图最大互不可达集

ans = n - maxmatch,其中二分图建图方法是拆入点和出点(实现时直接跑一次二分图就行,不用额外处理),注意**需要**传递闭包。方案?

#### 5.3.7 最大权闭合子图

# 5.4 匹配与网络流相关代码

### 5.4.1 二分图最大权匹配

```
namespace KM
   const int N=405;//点数
   typedef long long ll;//答案范围
   const ll inf=1e16;

#### 5.4.5 假带花树

一种错误的一般图最大匹配算法,但较难卡掉。推荐在时间不足时作为乱搞使用。

```
mt19937 rnd(3214);
vector<int> lj[N];
int lk[N],ed[N];
int n,m,cnt,i,t,x,y,ans,la;
bool dfs(int x)
{
   ed[x]=cnt;int v;
   shuffle(lj[x].begin(),lj[x].end(),rnd);
   for (auto u:lj[x]) if (ed[v=lk[u]]!=cnt)
       lk[v]=0, lk[u]=x, lk[x]=u;
       if (!v||dfs(v)) return 1;
       1k[v]=u,1k[u]=v,1k[x]=0;
   return 0;
int main()
   srand(time(0));la=-1;
   cin>>n>>m;
   while (m--) cin>>x>>y,lj[x].push_back(y),lj[y].push_back(x);
   while (la!=ans)
       memset(ed+1,0,n<<2);la=ans;
       for (i=1;i<=n;i++) if (!lk[i]) ans+=dfs(cnt=i);</pre>
   cout << ans << '\n';
   for (i=1;i<=n;i++) cout<<lk[i]<<"_{\sqcup}\n"[i==n];
```

### 5.4.6 Stoer-Wagner 全局最小割

无向图 G 的最小割为:一个去掉后可以使 G 变成两个连通分量,且边权和最小的边集的边权和。

 $O(n^3)$ 。 可优化到  $O(nm \log n)$ 。

```
#include "bits/stdc++.h"
```

```
using namespace std;
namespace StoerWagner
   const int N=602;//点数
   typedef int T;//边权和
   T \in [N][N], w[N];
   int ed[N],p[N],f[N];//f 仅输出方案用
   int getf(int u){return f[u]==u?u:f[u]=getf(f[u]);}
   template<class TT> pair<T,vector<int>> mincut(int n,const vector<tuple<int,int,TT>> &edges)//
        [1,n], 返回某一集合
   {
       vector<int> ans;ans.reserve(n);
       int i,j,m;
       Tr;
       r=numeric_limits<T>::max();
       for (i=1;i<=n;i++) memset(e[i]+1,0,n*sizeof e[0][0]);</pre>
       for (auto [u,v,w]:edges) e[u][v]+=w,e[v][u]+=w;
       fill_n(ed+1,n,0);
       iota(f+1,f+n+1,1);
       for (m=n;m>1;m--)
          fill_n(w+1,n,0);
          for (i=1;i<=n;i++) ed[i]&=2;</pre>
          for (i=1;i<=m;i++)</pre>
              int x=0;
              for (j=1;j<=n;j++) if (!ed[j]) break;x=j;</pre>
              for (j++;j<=n;j++) if (!ed[j]*w[j]>w[x]) x=j;
              ed[p[i]=x]=1;
              for (j=1;j<=n;j++) w[j]+=!ed[j]*e[x][j];</pre>
          }
          int s=p[m-1],t=p[m];
          if (r>w[t])
              r=w[t];ans.clear();
              for (i=1;i<=n;i++) if (getf(i)==getf(t)) ans.push_back(i);</pre>

```

# 5.5 缩点相关

#### 5.5.1 双极分解

无向图,图点双连通时对任意 s,t 存在。

含义:确定一个拓扑序,使得按这个拓扑序定向后,入度为 0 的只有 s,出度为 0 的只有 t。

```
vector<int> bipolar_orientation(const vector<pair<int, int>> &edges, int n, int s, int t)//[0,n)
   assert(s!=t);
   vector e(n, vector<int>());
   for (auto [u, v]:edges)
      e[u].push_back(v);
      e[v].push_back(u);
   int cur=1, i;
   vector<int> pre(n), low(n), p(n);
   pre[s]=1;
   vector<int> id;
   bool flg=0;
   function<void(int)> dfs=[&](int x)
      {
          pre[x]=++cur;
          low[x]=x;
          for (int y:e[x])
              flg|=y==s;
              if (pre[y]==0)
                 id.push_back(y);
                 dfs(y);
```

```
p[y]=x;
                  if (pre[low[y]] < pre[low[x]]) low[x] = low[y];</pre>
              else if (pre[y]!=0&&pre[y]<pre[low[x]]) low[x]=y;</pre>
       };
   dfs(t);
   if (!flg) return { };
   vector<int> sign(n, -1);
   vector<int> l(n), r(n);
   r[s]=t;
   1[t]=s;
   for (int v:id)
       if (sign[low[v]]==-1)
           l[v]=l[p[v]];
           r[1[v]]=v;
           1[p[v]]=v;
           r[v]=p[v];
           sign[p[v]]=1;
       }
       else
       {
           r[v]=r[p[v]];
           l[r[v]]=v;
           r[p[v]]=v;
           1[v]=p[v];
           sign[p[v]]=-1;
       }
   }
   vector<int> a(n);
   int x;
   for (i=0, x=s; i<n; x=r[x], i++) a[i]=x;</pre>
   vector<int> ia(n, -1), rd(n), cd(n);
   for (i=0; i<n; i++) ia[a[i]]=i;</pre>
   if (count(all(ia), -1)) return { };
   for (auto [u, v]:edges)
       if (ia[u]>ia[v]) swap(u, v);
       ++cd[u]; ++rd[v];
   for (i=0; i<n; i++) if (i!=s&&i!=t&&(!cd[i]||!rd[i])) return { };</pre>
   return a;
}
```

#### 5.5.2 点双

#### 一些结论:

判定一个图里是否有(点不重复)偶环:看其所有点双,若存在点数为偶数的或边数多于点数的点双,则存在偶环。

(无自环时)点双的边不交,边双的点不交。点双内的总点数 O(n),总边数为 m,边双内的总点数为 n,总边数不超过 m。

关于板子本身:

所有标号从 0 开始。

181

构造函数传入邻接表和边数,其中 pair 的 second 是边的标号,正反向编号相同,允许不连续但不能大于等于  $m_{\circ}$ 

不能处理有自环的情况。你可以直接在图中删除自环后传入。可以处理有重边的情况。

bcc\_node:每个点双包含的点(已验证);bcc\_edge:每个点双包含的边;bcc\_n:新图点数;ct:是否割点(已验证);blk:边所属点双标号。

```
struct node_bcc
{
   int n, id, tp, bcc_n;
   vector<vector<pair<int, int>>> e;
   vector<vector<int>> bcc_node, bcc_edge;
   vector<int> dfn, low, st, ed, blk, ct;
   node_bcc(const vector<vector<pair<int, int>>> &e, int m) :

```

## 5.5.4 Tarjan 强连通分量

未经验证。

所有标号从 0 开始。

构造函数传入邻接表,其中 pair 的 second 是边的标号。

与点边双不同的是,你可以任意传入 second,代码中不会使用它,仅用于新图区分边。可以处理有重边和自环的情况。

cc\_node:每个 SCC 包含的点(已验证); cc\_n:新图点数; cur\_e:新图边表; blk:点所属 SCC 标号。

```
struct scc
   int n, id, tp, cc_n;
   vector<vector<pair<int, int>>> e, cur_e;
   vector<vector<int>> cc_node;
   vector<int> dfn, low, st, ed, blk;
   void dfs(int u)
       dfn[u] = low[u] = id++;
       st[tp++] = u; ed[u] = 1;
       for (auto [v, w] : e[u]) if (dfn[v] == -1)
          dfs(v);
          cmin(low[u], low[v]);
       else if (ed[v]) cmin(low[u], dfn[v]);
       if (low[u] == dfn[u])
          cc_node.push_back({ });
          do
          {
              int v = st[--tp];
              ed[v] = 0;
              blk[v] = cc_n;
              cc_node[cc_n].push_back(v);
          } while (st[tp] != u);
          cc_n++;
       }
   scc(const vector<vector<pair<int, int>>> &e) :n(e.size()), id(0), tp(0), cc_n(0),
       e(e), cur_e(n), dfn(n, -1), low(dfn), st(n), ed(n), blk(n)
       for (int i = 0; i < n; i++) for (auto [v, w] : e[i]) assert(v >= 0 && v < n);
       for (int i = 0; i < n; i++) if (dfn[i] == -1) dfs(i);</pre>
       reverse(all(cc_node));

## 5.5.7 广义圆方树

建议使用点双来做这个。你只需要对每个点双建一个虚点,向点双内所有原点连边,就得到了 广义圆方树。

#### **5.5.8** 2-sat

支持添加一个条件 add(u,x,v,y),表示  $a_u=x\Rightarrow a_v=y$ 。支持设定一个变量的值。O(n+m),O(n+m)。

```
struct sat
```

```
vector<vector<int>> e;
   vector<int> dfn, low, st, f, ed;
   int fs, tp, id, n;
   sat(int n) : n(n), e(n * 2), dfn(n * 2, -1), low(n * 2), st(n * 2), f(n * 2, -1), ed(n * 2), fs
       (0), tp(-1), id(0) { }
   void dfs(int u)
       dfn[u] = low[u] = id++;
       ed[u] = 1; st[++tp] = u;
       for (int v : e[u]) if (dfn[v] != -1)
          if (ed[v]) low[u] = min(low[u], dfn[v]);
       }
       else dfs(v), low[u] = min(low[u], low[v]);
       if (dfn[u] == low[u])
       {
          do
          {
              f[st[tp]] = fs;
              ed[st[tp]] = 0;
          } while (st[tp--] != u);
          ++fs;
      }
   void add(int u, bool x, int v, bool y)
       assert(u >= 0 && u < n && v >= 0 && v < n);
       e[u + x * n].push_back(v + y * n);
       e[v + (y ^1) * n].push_back(u + (x ^1) * n);
   void set(int u, bool x)
       assert(u \ge 0 \&\& u < n);
       e[u + (x ^1) * n].push_back(u + x * n);
   vector<int> getans()
       int i;
       for (i = 0; i < n * 2; i++) if (dfn[i] == -1) dfs(i);</pre>
       vector<int> r(n);
       for (i = 0; i < n; i++)</pre>
          if (f[i] == f[i + n]) return { };
          r[i] = f[i] > f[i + n];
      return r;
   }
};
```

## 5.5.9 Kosaraju 强连通分量(bitset 优化)

```
实用意义不大。O(\frac{n^2}{w}),O(\frac{n^2}{w})。
```

```
void dfs1(int x)
{
```

```
int i; ed[x] = 0;
   for (i = (lj[x] & ed)._Find_first(); i <= n; i = (lj[x] & ed)._Find_next(i)) dfs1(i);</pre>
   sx[--tp] = x;
void dfs2(int x)
   int i; ed[x] = 0; tv[f[x] = f[0]] += v[x];
   for (i = (fj[x] & ed)._Find_first(); i <= n; i = (fj[x] & ed)._Find_next(i)) dfs2(i);

       return cmp(st[g][u], st[g][v - (1 << g)]);</pre>
   int dis(int u, int v)
       return dep[u] + dep[v] - (dep[lca(u, v)] << 1);</pre>
   }
using LCA::lca, LCA::fun, LCA::dis;
```

## 5.6.2 换根树剖

本质是对普通树剖在换根后的子树进行分类讨论。 设预处理的根是 u, 当前根是 v, 那么 w 的子树如下:

- 1. w = v, dfn 区间为 [1, n]。
- 2. w 在 u,v 之间,dfn 区间为 [1,n] 去掉 w 前往 v 方向的子树。找到这个子树的方法见 find 函数。
- 3. 其余情况, dfn 区间和原来一致。

```
int find(int x,int y)//找到 y 向 x 的子树
{
    while ((top[x]!=top[y])&&(f[top[x]]!=y)) x=f[top[x]];
    if (top[x]==top[y]) return hc[y];
    return top[x];
}
```

# 5.6.3 树上启发式合并, DSU on tree

一种过时的、基于两次 dfs 的写法,在复杂度要求不严时不如直接存储 set。 流程:

- 1. dfs 轻子树计算答案,并清空全局统计信息。
- 2. dfs 重子树统计答案和全局信息。
- 3. dfs 轻子树统计全局信息。

```
void dfs1(int x)
{
   siz[x]=zdep[x]=1;
   for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x])
      dep[lj[i]] = dep[f[lj[i]] = x] + 1;
      dfs1(lj[i]);
      siz[x]+=siz[lj[i]];
      if (siz[hc[x]]<siz[lj[i]]) hc[x]=lj[i];</pre>
      zdep[x]=max(zdep[x],zdep[lj[i]]+1);
   }
void cal(int x)
{
   int i;
   dl[tou=wei=1]=x;
   while (tou<=wei)</pre>
      ++dp[dep[x=dl[tou++]]];
      for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x]) dl[++wei]=lj[i];
   }
void dfs2(int x)
   if (!hc[x])
      if (++dp[dep[x]]>dp[zd]) zd=dep[x];
      return;
   }
   for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x]))
   {
      dfs2(lj[i]);
      memset(dp+dep[lj[i]],0,zdep[lj[i]]<<2);
   dfs2(hc[x]);
   dp[dep[x]]=1;
   if (dp[zd] <=1) zd=dep[x];</pre>
   for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x])) cal(lj[i]);
   ans[x]=zd-dep[x];
}
```

### 5.6.4 长链剖分(k 级祖先)

 $O(n \log n + q)$ , O(n).

```
void dfs1(int x)
   int i;
   for (i = 1; i \le er[dep[x] - 1]; i++) f[x][i] = f[f[x][i - 1]][i - 1]; md[x] = dep[x];
   for (i = fir[x]; i; i = nxt[i]) { dep[lj[i]] = dep[x] + 1; dfs1(lj[i]); if (md[lj[i]] > md[dc[
       x]]) dc[x] = lj[i]; }
   if (dc[x]) md[x] = md[dc[x]];
}
void dfs2(int x)
   int i;
   if (dc[x])
       top[dc[x]] = top[x];
       dfs2(dc[x]);
       for (i = fir[x]; i; i = nxt[i]) if (lj[i] != dc[x]) dfs2(top[lj[i]] = lj[i]);
   if (x == top[x])
   {
       c = md[x] - dep[x]; y = x; up[x].push_back(x); down[x].push_back(x);
       for (i = 1; (i <= c) && (y = f[y][0]); i++) up[x].push_back(y); y = x;
       for (i = 1; i <= c; i++) down[x].push_back(y = dc[y]);</pre>
}
int main()
   int n, q, ans = 0, x, y, c, i;
   11 ta = 0;
   cin >> n >> q >> s;
   for (i = 1; i <= n; i++) { cin >> f[i][0]; if (f[i][0] == 0) rt = i; else add(f[i][0], i); }
   for (i = 2; i <= n; i++) er[i] = er[i >> 1] + 1; dep[rt] = 1;
   dfs1(rt); dfs2(top[rt] = rt);
   for (i = 1; i <= q; i++)</pre>
       x = (get(s) \hat{ans}) \% n + 1; y = (get(s) \hat{ans}) \% dep[x];
       //此时计算 x 的 y 级祖先。结果在 ans 中。
       if (y == 0) { ans = x; ta ^= (11)i * ans; continue; }
       c = dep[x] - y; x = top[f[x][er[y]]];
       if (dep[x] > c) ans = up[x][dep[x] - c]; else ans = down[x][c - dep[x]];
       ta ^= (11)i * ans;
   cout << ta << endl;</pre>
```

## 5.6.5 长链剖分(dp 合并)

一种常见的实现方法是用指针指向同一片数组区域,使得从链头到链尾正好指向连续的一段数组,就不需要计算偏移量了。

```
O(n), O(n).
```

```
void dfs1(int x)
{
    top[x]=1;
```

```
for (int i=fir[x];i;i=nxt[i]) if (!top[lj[i]])
       dfs1(lj[i]);
       if (len[lj[i]]>len[hc[x]]) hc[x]=lj[i];
   len[x]=len[hc[x]]+1;top[hc[x]]=0;
void dfs2(int x)
   *f[x]=1;gs[x]=1;
   if (!hc[x]) return;
   ed[x]=1;f[hc[x]]=f[x]+1;
   for (int i=fir[x];i;i=nxt[i]) if (!ed[lj[i]]) dfs2(lj[i]);
   ans [x]=ans [hc[x]]+1; gs[x]=gs[hc[x]];
   if (gs[x]==1) ans[x]=0;
   for (int i=fir[x];i;i=nxt[i]) if ((!ed[lj[i]])&&(lj[i]!=hc[x]))
       int v=lj[i],*p;
       for (int j=0;j<len[v];j++)</pre>
          *(p=f[x]+j+1)+=*(f[v]+j);
          if (j+1==ans[x]) {gs[x]=*p;continue;}
          if ((*p>gs[x])||(*p==gs[x])\&\&(j+1<ans[x])) \{gs[x]=*p;ans[x]=j+1;\}
   gs[x]=*(f[x]+ans[x]);
   ed[x]=0;
```

### 5.6.6 LCT

 $O(n\log n)$ ,O(n)。
makeroot 会变根,split 会把 y 变根,findroot 会把根变根,link 会把 x,y 变根(y 是新的),cut 会把 x,y 变根(x 是新的),注意 swap 子节点可能要 pushup。
代码为动态割边割点。

```
#include "bits/stdc++.h"
using namespace std;
template<int N,class info,class tag> struct LCT
   int f[N],c[N][2];
   info s[N], v[N];
#ifdef Rev
   info rs[N];
#endif
   tag tg[N];
   bool rev[N],lz[N];
   void init(int n,info *a)
       for (int i=0; i<=n; i++)</pre>
       {
          rev[i]=lz[i]=0;
          f[i]=c[i][0]=c[i][1]=0;
          s[i]=v[i]=a[i];
#ifdef Rev
          rs[i]=a[i];
```

```
#endif
   }
   bool nroot(int x) const
       return c[f[x]][0]==x||c[f[x]][1]==x;
   }
   void pushup(int x)
       int lc=c[x][0],rc=c[x][1];
      s[x]=v[x];
#ifdef Rev
      rs[x]=v[x];
#endif
       if (1c)
          s[x]=s[lc]+s[x];
#ifdef Rev
          rs[x]=rs[x]+rs[lc];
#endif
      }
      if (rc)
          s[x]=s[x]+s[rc];
#ifdef Rev
          rs[x]=rs[rc]+rs[x];
#endif
      }
   void swp(int x)
       swap(c[x][0],c[x][1]);
#ifdef Rev
      swap(s[x],rs[x]);
#endif
      rev[x]^=1;
   void pushdown(int x)
       if (rev[x])
          for (int y:c[x]) if (y) swp(y);
          rev[x]=0;
      }
      if (lz[x])

```

### 5.6.7 带子树的 LCT

 $O(n \log n)$ , O(n)。 你需要实现的是 info 类的 +,+=,-=。

- 1. info 维护的是从上往下的一条链以及这条链挂着的所有轻子树的信息。
- 2. a+b 表示两条链合并后的信息,其中 a 接近根。
- 3. a+=b 表示一条链合并了一个轻子树,即 b 是 a 链尾的子结点。
- 4. a-=b 表示一条链移除了一个轻子树,即 b 是 a 链尾的子节点。

如果有边权,将边(u,v)当成点并与u,v分别连边。

代码对应题意:

对于满足  $0 \le e \le N-2$  的整数 e,定义  $f_e(x) = b_e x + c_e$ 。 设  $e_0, e_1, \ldots, e_k$  为从顶点 x 到顶点 y 的简单路径上的边,按顺序排列,并定义

$$P(x,y) = f_{e_0}(f_{e_1}(\dots f_{e_k}(a_y)\dots)).$$

按给定顺序处理 Q 个查询。查询有两种类型:

• 0 w x r: 将 a<sub>w</sub> 更新为 x, 然后输出

$$\left(\sum_{v=0}^{N-1} P(r, v)\right) \mod 998244353.$$

• 1 e y z r: 将  $(b_e, c_e)$  更新为 (y, z),然后输出

$$\left(\sum_{v=0}^{N-1} P(r, v)\right) \mod 998244353.$$

```
template < class info > struct LCT
{
   int n;
   vector < info > sum, sum_rev, val, sum_oth;
   vector < int > f, lz;
```

```
vector<array<int, 2>> c;

### 5.6.10 虚树

传入点标号列表,返回虚树边表。自动认为 1 是根,标号从 1 开始。 需要注意的是:在清空的时候需要同时考虑点列表和边表,都清空一下。 你需要提供的是: dep,lca,dfn。  $O(n + \sum k \log n)$ , O(n)。

```
vector<pair<int, int>> get_tree(vector<int> a)
   vector<pair<int, int>> edges;
   sort(all(a), [&](int u, int v) { return dfn[u] < dfn[v]; });</pre>
   vector<int> st(a.size()+2);
   int tp=0;
   auto ins=[&](int u)
      {
          if (tp==0)
          {
              st[tp=1]=u;
              return;
          int v=lca(st[tp], u);
          while (tp>1&&dep[v]<dep[st[tp-1]])</pre>
              edges.emplace_back(st[tp-1], st[tp]);
              --tp;
          }
          if (dep[v] < dep[st[tp]]) edges.emplace_back(v, st[tp--]);</pre>
          if (!tp||st[tp]!=v) st[++tp]=v;
          st[++tp]=u;
   if (a[0]!=1) st[tp=1]=1;//先行添加根节点
   for (int u:a) ins(u);
   if (tp) while (--tp) edges.emplace_back(st[tp], st[tp+1]);//回溯
   return edges;
```

## 5.6.11 点分治

点分治板子的参考意义不大。  $O(n \log n)$ , O(n)。

```
int siz[N], dep[N];
int n, ksiz, md, rt, mn;
bool ed[N];
void find(int u)
{
    ed[u] = 1; siz[u] = 1;
    int mx = 0;
    for (int v : e[u]) if (!ed[v])
    {
        find(v);
        siz[u] += siz[v];
        mx = max(mx, siz[v]);
    }
    mx = max(mx, ksiz - siz[u]);
    if (mn > mx) mn = mx, rt = u;
    ed[u] = 0;
```

```
void cal(int u)
   md = max(md, dep[u]);
   ed[u] = 1; ++cnt[dep[u]];
   for (int v : e[u]) if (!ed[v])
       dep[v] = dep[u] + 1;
       cal(v);
   ed[u] = 0;
void solve(int u)
   mn = 1e9;
   find(u);
   ed[rt] = 1;
   vector<int> c;
   for (int v : e[rt]) if (!ed[v])
       c.push_back(v);
       if (siz[v] >= siz[rt]) siz[v] = siz[u] - siz[rt];
   sort(all(c), [&](const int &a, const int &b) {return siz[a] < siz[b]; });</pre>
   NTT::Q a(vector<ui>{1});
   NT::Q b(vector<ui>{1});
   for (int v : c)
       md = 0; dep[v] = 1;
       cal(v); ++md;
       vector<ui> d(cnt, cnt + md);
       NTT::Q e(d);
       NT::Q f(d);
       auto g = e & a;
       auto h = f & b;
       for (int i = 0; i < g.a.size(); i++) r1[i] = (r1[i] + g.a[i]) % NTT::p;</pre>

### 5.6.13 (基环) 树哈希

有根树返回每个子树的哈希值,无根树返回树的哈希值(长度至多为 2 的 vector),基环树返回图的哈希值(长度等于环长的 vector)。

```
vector<int> tree_hash(const vector<vector<int>>& e, int root)//[0,n)
   int n = e.size();
   static map<vector<int>, int> mp;
   static int id = 0;
   vector<int> h(n), ed(n);
   function<void(int)> dfs = [&](int u)
          ed[u] = 1;
          vector<int> c;
          for (int v : e[u]) if (!ed[v])
              dfs(v);
              c.push_back(h[v]);
          }
          sort(all(c));
          if (!mp.count(c)) mp[c] = id++;
          h[u] = mp[c];
       };
   dfs(root);
   return h;
vector<int> tree_hash(const vector<vector<int>>& e)//[0,n)
   int n = e.size();
   if (n == 0) return { };
   vector<int> sz(n), mx(n);
   function<void(int)> dfs = [&](int u)
       {
          sz[u] = 1;
          for (int v : e[u]) if (!sz[v])
              dfs(v);
              sz[u] += sz[v];
              cmax(mx[u], sz[v]);
          cmax(mx[u], n - sz[u]);
       };
   dfs(0);
   int m = *min_element(all(mx)), i;
   vector<int> rt;
   for (i = 0;i < n;i++) if (mx[i] == m) rt.push_back(i);</pre>
   for (int& u : rt) u = tree_hash(e, u)[u];
   sort(all(rt));
   return rt;
template<class T> void min_order(vector<T>& a)
   int n = a.size(), i, j, k;
   a.resize(n * 2);
```

```
for (i = 0;i < n;i++) a[i + n] = a[i];</pre>

}
```

#### 5.7.3 回路计数(BEST 定理)/生成树计数

 $O(n^3)$ ,  $O(n^2)$ .

以 u 为起点的欧拉回路个数  $sum = T(u) \times \prod_{v=1}^{n} (out(v) - 1)!$ ,其中 T(u) 是以 u 为根的内向树个数(出度矩阵-邻接矩阵),out(v) 是 v 的出度。若允许循环同构(如  $1 \to 2 \to 1 \to 3 \to 1$  与  $1 \to 3 \to 1 \to 2 \to 1$ ),还需多乘 out(u)。

这里的部分代码是未经验证的。

```
11 det(vector<vector<11>>> b)
{
   ll r=1;
   int n=b.size(), i, j, k;
   for (i=0; i<n; i++)</pre>
       for (j=i; j<n; j++) if (b[j][i]) break;</pre>
       if (j==n) return 0;
       swap(b[j], b[i]);
       if (j!=i) r=(p-r)%p;
       r=r*b[i][i]%p;
       b[i][i]=ksm(b[i][i], p-2);
       for (j=n-1; j>=i; j--) b[i][j]=b[i][j]*b[i][i]%p;
       for (j=i+1; j<n; j++) for (k=n-1; k>=i; k--) b[j][k]=(b[j][k]+(p-b[j][i])*b[i][k])%p;
   return r;

    return det(b);
}</pre>
```

## 5.8 三/四元环计数

不能处理有重边和自环的情况。

 $O(m\sqrt{m})$ , O(n+m).

注意四元环数的是边四元环。点四元环需要去掉四点完全图个数 \*2,似乎不太能做?三元环是可以枚举的,你可以在 ans 改变时记录三元环 (i,u,v)。

```
11 triple(const vector<pair<int,int>> &edges)//start from 0
   int n=0,i;
   for (auto [u,v]:edges) n=max({n,u,v});
   vector<int> d(n),id(n),rk(n),cnt(n);
   vector<vector<int>> e(n);
   for (auto [u,v]:edges) ++d[u],++d[v];
   iota(all(id),0); sort(all(id),[&](int x,int y) { return d[x]<d[y]; });</pre>
   for (i=0; i<n; i++) rk[id[i]]=i;</pre>
   for (auto [u,v]:edges)
       if (rk[u]>rk[v]) swap(u,v);
       e[u].push_back(v);
   ll ans=0;
   for (i=0; i<n; i++)</pre>
       for (int u:e[i]) cnt[u]=1;
       for (int u:e[i]) for (int v:e[u]) ans+=cnt[v];
       for (int u:e[i]) cnt[u]=0;
   return ans;
11 quadruple(const vector<pair<int,int>> &edges)
   int n=0,i;
   for (auto [u,v]:edges) n=max({n,u,v});
   vector<int> d(n),id(n),rk(n),cnt(n);
   vector<vector<int>> e(n),lk(n);
   for (auto [u,v]:edges) ++d[u],++d[v];
   iota(all(id),0); sort(all(id),[&](int x,int y) { return d[x]<d[y]; });</pre>
   for (i=0; i<n; i++) rk[id[i]]=i;</pre>
   for (auto [u,v]:edges)
   {
       if (rk[u]>rk[v]) swap(u,v);
       e[u].push_back(v);
```

```
lk[u].push_back(v);
       lk[v].push_back(u);
   }
   ll ans=0;
   for (i=0; i<n; i++)</pre>
       for (int u:lk[i]) for (int v:e[u]) if (rk[v]>rk[i]) ans+=cnt[v]++;
       for (int u:lk[i]) for (int v:e[u]) cnt[v]=0;

   i = 0;
   for (auto [u, v] : edges)
       if (rk[u] > rk[v]) swap(u, v);
       e[u].push_back({v, i});
       lk[u].push_back({v, i});
       lk[v].push_back({u, i});
       ++i;
   int m = edges.size();
   vector<ll> ans(m);
   for (i = 0; i < n; i++)</pre>
       for (auto [u, w1] : lk[i]) for (auto [v, w2] : e[u]) if (rk[v] > rk[i])
          cnt[v] += c[w1] * c[w2];
       for (auto [u, w1] : lk[i]) for (auto [v, w2] : e[u]) if (rk[v] > rk[i])
          ans[w1] += (cnt[v] - c[w1] * c[w2]) * c[w2];
          ans[w2] += (cnt[v] - c[w1] * c[w2]) * c[w1];
       for (auto [u, w1] : lk[i]) for (auto [v, w2] : e[u]) if (rk[v] > rk[i]) cnt[v] = 0;
   map<pair<int, int>, ll> mp;
   for (i = 0;i < m;i++) mp[edges[i]] = ans[i];</pre>
```

```
return mp;
}
int main()
   ios::sync_with_stdio(0); cin.tie(0);
   cout << fixed << setprecision(15);</pre>
   int n, m, i;
   cin >> n >> m;
   vector<pair<int, int>> eg(m);
   cin >> eg;
   auto mp = quadruple(eg);
   for (i = 0;i < m;i++)</pre>
       auto [u, v] = eg[i];
       if (u > v) swap(u, v);
       cout << mp[{u, v}] << "_{\sqcup} \n"[i + 1 == m];
   }
}
```

### 5.9 支配树

u 支配 v 指的是从 S 到 v 的路径必然经过 u。支配树是保持支配关系不变的树,其中 s 是根,idom[u] 是 u 的父节点。

DAG 版:  $O(m \log n)$ ,  $O(n \log n)$ 。

```
int lca(int x, int y)
{
   int i;
   if (dep[x] < dep[y]) swap(x, y);
   for (i = lm[x]; dep[x] != dep[y]; i--) if (dep[f[x][i]] >= dep[y]) x = f[x][i];
   if (x == y) return x;
   for (i = lm[x]; f[x][0] != f[y][0]; i--) if (f[x][i] != f[y][i])
       x = f[x][i]; y = f[y][i];
   return f[x][0];
void dfs(int x)
   s[x] = 1;
   int i;
   for (i = sfir[x]; i; i = snxt[i])
       dfs(slj[i]);
       s[x] += s[slj[i]];
   }
}
int main()
   dep[0] = -1;
   cin >> n;
   for (i = 1; i <= n; i++)</pre>
       cin >> x;
       while (x)
       {
```

```
add(x, i);
          cin >> x;
       }
   }
   dl[tou = wei = 1] = ++n;
   for (i = 1; i < n; i++) if (!rd[i]) add(n, i);</pre>
   while (tou <= wei)</pre>
       for (i = fir[x = dl[tou++]]; i; i = nxt[i]) if (--rd[lj[i]] == 0) dl[++wei] = lj[i];
       if (i = ffir[x])
          y = flj[i];
          while (i = fnxt[i]) y = lca(y, flj[i]);
          f[x][0] = y;
       else y = 0;
       sadd(y, x);
       f[x][0] = y;
       for (i = 1; i \le 16; i++) if (0 == (f[x][i] = f[f[x][i - 1])[i - 1]))
          lm[x] = i;
          break;
       dep[x] = dep[y] + 1;
   }
   dfs(n);
   for (i = 1; i < n; i++) printf("d\n", s[i] - 1);
}
```

#### 一般图:

```
vector<int> dom_tree(vector<vector<int>> e, int s)//[1,n]
   int n = e.size() - 1, i, id = 0;
   vector<vector<int>> c(n + 1), buc(c), ie(c);
   vector < int > mn(n + 1), f(n + 1), sdom(n + 1), idom(n + 1), dfn(n + 1), nfd(n + 1), pv(n + 1),
   auto cmp = [&](int x, int y) {return dfn[x] < dfn[y] ? x : y; };</pre>
   auto cmp2 = [&](int x, int y) {return dfn[sdom[x]] < dfn[sdom[y]] ? x : y; };</pre>
   function<void(int)> getf = [&](int u) {
       if (f[u] == u) return;
       getf(f[u]);
       mn[u] = cmp2(mn[u], mn[f[u]]);
       f[u] = f[f[u]];
   };
   for (i = 1; i <= n; i++) mn[i] = f[i] = i;</pre>
   function<void(int)> dfs = [&](int u) {
       ed[u] = 1;
       for (int v : e[u]) if (!ed[v]) dfs(v);
   };
   dfs(s);
   for (i = 1; i <= n; i++) if (ed[i]) erase_if(e[i], [&](int v) { return !ed[v]; });</pre>
   else e[i].clear();
   for (i = 1; i <= n; i++) for (int v : e[i]) ie[v].push_back(i);</pre>
   dfs = [\&](int u) {
      nfd[dfn[u] = ++id] = u;
       for (int v : e[u]) if (!dfn[v]) dfs(v), c[u].push_back(v);
   };
```

```
dfs(s); dfn[0] = 1e9;
   for (i = id; i; i--)
       int u = nfd[i], w = 0;
       for (int v : ie[u])
           sdom[u] = cmp(sdom[u], v);
           if (dfn[v] > dfn[u])
              getf(v);
              w = cmp2(w, mn[v]);
       sdom[u] = cmp(sdom[u], sdom[w]);
       buc[sdom[u]].push_back(u);
       for (int v : buc[u]) getf(v), pv[v] = mn[v];
       for (int v : c[u]) f[v] = u, mn[v] = cmp2(mn[v], mn[u]);
   for (i = 1; i <= n; i++) idom[nfd[i]] = (sdom[pv[nfd[i]]] == sdom[nfd[i]]) ? sdom[nfd[i]] :</pre>
       idom[pv[nfd[i]]];
   idom[s] = s;
   return idom;
int main()
   int n, m, s;
   cin >> n >> m >> s; ++s;
   vector<vector<int>> e(n + 1);
   for (int i = 1; i <= m; i++)</pre>
       int u, v;
       cin >> u >> v; ++u; ++v;
       e[u].push_back(v);
   auto r = dom_tree(e, s);
   for (int i = 1; i <= n; i++) cout << r[i] - 1 << "_{\sqcup} \setminus n"[i == n];
```

## 5.10 prufer 与树的互相转化

```
O(n), O(n).
```

```
vector<int> edges_to_prufer(const vector<pair<int,int>> &eg)//[1,n], 定根为 n
{
    int n=eg.size()+1,i,j,k;
    vector<int> fir(n+1),nxt(n*2+1),e(n*2+1),rd(n+1);
    int cnt=0;
    for (auto [u,v]:eg)
    {
        e[++cnt]=v;nxt[cnt]=fir[u];fir[u]=cnt;++rd[v];
        e[++cnt]=u;nxt[cnt]=fir[v];fir[v]=cnt;++rd[u];
    }
    for (i=1;i<=n;i++) if (rd[i]==1) break;
    int u=i;
    vector<int> r;r.reserve(n-2);
    for (j=1;j<n-1;j++)
    {</pre>
```

```
for (k=fir[u],u=rd[u]=0;k;k=nxt[k]) if (rd[e[k]])
          r.push_back(e[k]);
          if ((--rd[e[k]]==1)\&\&(e[k]<i)) u=e[k];
       if (!u) { while (rd[i]!=1) ++i;u=i;}
   }
   return r;
}
vector<pair<int,int>> prufer_to_edges(const vector<int> &p)//[1,n], 定根为 n
   int n=p.size(),i,j,k;
   int m=n+3;
   vector<int> cs(m);
   for (i=0;i<n;i++) ++cs[p[i]];</pre>
   i=0;
   while (cs[++i]);
   int u=i,v;
   vector<pair<int,int>> r;
   r.reserve(n-2);
   for (j=0;j<n;j++)</pre>
       cs[u]=1e9;
       r.push_back({u,v=p[j]});
       if ((--cs[v]==0)\&\&(v<i)) u=v;
       if (v!=u) {while (cs[i]) ++i;u=i;}
   r.push_back({u,n+2});
   return r;
}
```

## 5.11 最小密度环

求所有环中边权和除以边数最少的,O(nm)。更常用的做法是二分 spfa。

```
#include "bits/stdc++.h"
using namespace std;
const int N=3e3+5,M=1e4+5;
const double inf=1e18;
int u[M],v[M];
double f[N][N],w[M];
int main()
{
   ios::sync_with_stdio(0);cin.tie(0);
   cout<<setiosflags(ios::fixed)<<setprecision(8);</pre>
   int n,m,i,j;
   cin>>n>>m;
   for (i=1;i<=m;i++) cin>>u[i]>>v[i]>>w[i];
   ++n;
   for (i=1;i<=n;i++)</pre>
       fill_n(f[i]+1,n,inf);
       for (j=1;j<=m;j++) f[i][v[j]]=min(f[i][v[j]],f[i-1][u[j]]+w[j]);</pre>
   double ans=inf;
   for (i=1;i<n;i++) if (f[n][i]!=inf)</pre>
   {
```

```
double r=-inf;
    for (j=1;j<n;j++) r=max(r,(f[n][i]-f[j][i])/(n-j));
    ans=min(ans,r);
}
cout<<ans<<endl;
}</pre>
```

### 5.12 点染色

结论:  $\chi(G) \leq \Delta(G) + 1$ , 其中  $\Delta(G)$  是图的最大度。只有奇圈和完全图取等。构造方案只能爆搜。

```
vector<int> chromatic_number(int n,const vector<pair<int,int>> &edges)//[0,n)
   vector r(n,-1), cur(n,-1);
   vector<vector<int>> e(n);
   int ans=0,i;
   for (auto [u,v]:edges) e[u].push_back(v),e[v].push_back(u);
   for (i=0;i<n;i++) ans=max(ans,(int)e[i].size());</pre>
   vector p(n,vector(ans,0));
   function<void(int)> dfs=[&](int u)
       int col=u?*max_element(cur.begin(),cur.begin()+u)+1:0;
       if (col>=ans) return;
       if (u==n)
          r=cur;
          ans=col;
          return;
       }
       for (int i=0;i<=col;i++) if (!p[u][i])</pre>
          cur[u]=i;
          for (int v:e[u]) ++p[v][i];
          dfs(u+1);
          for (int v:e[u]) --p[v][i];
   };
   dfs(0);
   return r;
}
```

## 5.13 最大独立集

爆搜。

```
vector<int> indep_set(int n,const vector<pair<int,int>> &edges)//[0,n)
{
    vector<vector<int>> e(n);
    mt19937 rnd(998);
    vector<int>> p(n),q(n),ed(n);
    iota(all(p),0);
    shuffle(all(p),rnd);
    for (int i=0;i<n;i++) q[p[i]]=i;</pre>
```

```
for (auto [u,v]:edges)
   e[p[u]].push_back(p[v]);
   e[p[v]].push_back(p[u]);
vector<int> r,cur;
function<void(int)> dfs=[&](int u)
   if (cur.size()+n-u<=r.size()) return;</pre>
   if (u==n)
       r=cur;
       return;
   }
   if (!ed[u])
       cur.push_back(u);
       for (int v:e[u]) ++ed[v];
       dfs(u+1);
       for (int v:e[u]) --ed[v];
       cur.pop_back();
   if (ed[u]||e[u].size()) dfs(u+1);
};dfs(0);
for (int &x:r) x=q[x];
sort(all(r));
return r;
```

### 5.14 弦图

单纯点: v 和 v 邻点构成团。

完美消除序列:  $v_i$  在  $\{v_i, v_{i+1}, \cdots, v_n\}$  为单纯点。

 $N(v_i) = \{v_i | j > i \land (v_i, v_j) \in E\}, next(v_i) \bowtie N(v_i)$  最靠前的点。

极大团一定是  $\{v\} \cup N(v)$  。

最大团大小等于色数。

弦图判定: 等价于是否存在完美消除序列。首先求出一个完美消除序列,然后判定是否合法。 判定方法: 设  $v_{i+1}, \dots, v_n$  中与  $v_i$  相邻的依次为  $v_1', \dots, v_m'$ 。只需判断是否  $v_1'$  与  $v_2', \dots, v_m'$  相邻。

LexBFS 算法 (我不会写)

每个点有一个字符串 label,初始为 0。从 i=n 到 i=1 确定,选 label 字典序最大的 u,再 把 u 邻点的 label 后面接一个 i。

最大势算法: 从  $v_n$  求到  $v_1$ ,设  $label_i$  表示 i 与多少个已选点相邻,每次选  $label_i$  最大的点。弦图极大团:  $\{v|\forall next(w)=v,|N(v)|\geq |N(w)|\}$ 。选出的集合为基本点,按上述极大团构造。弦图染色: 从  $v_n$  到  $v_1$  依次选最小可染的色。

最大独立集: 从  $v_1$  到  $v_n$  能选就选。

最小团覆盖: 设最大独立集为  $\{p_m\}$ ,最小团覆盖为  $\{\{p_i\} \cup N(p_i)\}$ 。

区间图:两个区间有边当且仅当交集非空。

区间图是弦图。

代码如下:

```
namespace chordal_graph//下标从 1 开始
```

```
const int N=1e5+2;//点数
bool ed[N];
vector<int> e[N];
int n;
void init(const vector<pair<int,int>> &edges)
   n=0;
   for (auto [u,v]:edges) n=max({n,u,v});
   for (int i=1;i<=n;i++) e[i].clear();</pre>
   for (auto [u,v]:edges) e[u].push_back(v),e[v].push_back(u);
vector<int> perfect_seq(const vector<pair<int,int>> &edges)//MCS
   init(edges);
   static int d[N];

          for (int v:e[w]) ee[v]=0;
      return 1;
   }
   bool check_chordal(const vector<pair<int,int>> &edges) {return check_perfect_seq(perfect_seq(
       edges));}
   vector<int> color(int _n,const vector<pair<int,int>> &edges)//返回长度为 _n+1。其中 0 无意义
      auto a=perfect_seq(edges);
      reverse(all(a));
      memset(ed+1,0,n*sizeof ed[0]);
      vector<int> r(_n+1);
      for (int u:a)
          for (int v:e[u]) ed[r[v]]=1;
          int x=1;
          while (ed[x]) ++x;
          r[u]=x;
          for (int v:e[u]) ed[r[v]]=0;
      for (int i=n+1;i<=_n;i++) r[i]=1;</pre>
      return r;
   vector<int> max_independent(int _n,const vector<pair<int,int>> &edges)//注意有孤立点这种奇怪东
      auto a=perfect_seq(edges);
      memset(ed+1,0,n*sizeof ed[0]);
      vector<int> r;
      for (int u:a) if (!ed[u])
          r.push_back(u);
          for (int v:e[u]) ed[v]=1;
      for (int i=n+1;i<=_n;i++) r.push_back(i);</pre>
      return r;
   }
using chordal_graph::check_chordal,chordal_graph::color,chordal_graph::max_independent;
```

## 6 计算几何

## 6.1 自适应 simpson 法

sim(l,r) 计算  $\int_{l}^{r} f(x) dx$ 

```
const db eps=1e-7;
db sl,sr,sm,a;
db f(db x)
{
    return pow(x,a/x-x);
}
db g(db l,db r)
{
    db mid=(l+r)*0.5;
    return (f(l)+f(r)+f(mid)*4)/6*(r-1);
}
db sim(db l,db r)
{
    db mid=(l+r)*0.5;
    sl=g(l,mid);sr=g(mid,r);sm=g(l,r);
    if (abs(sl+sr-sm)<eps) return sl+sr;
    return sim(l,mid)+sim(mid,r);
}</pre>
```

### 6.2 计算几何全

功能其实比较少,因为实际遇到的几何题不多。最有用的可能是闵可夫斯基和合并凸包,和常规的线段判交之类的。其余功能最好直接使用 HDU 板。

```
namespace geometry//不要用 int!
#define tmpl template<class T>
   typedef long long 11;
   typedef long double db;
   const db eps = 1e-6;
#define all(x) (x).begin(),(x).end()
   inline int sgn(const 11 &x)
      if (x < 0) return -1;
      return x > 0;
   inline int sgn(const db &x)
      if (fabs(x) < eps) return 0;</pre>
      return x > 0 ? 1 : -1;
   tmpl struct point//* 为叉乘, & 为点乘, 只允许使用 (long )double 和 11
      T x, y;
      point() { }
      point(T a, T b) :x(a), y(b) { }
      operator point<ll>() const { return point<ll>(x, y); }
      operator point<db>() const { return point<db>(x, y); }
      point<T> operator+(const point<T> &o) const { return point(x + o.x, y + o.y); }
      point<T> operator-(const point<T> &o) const { return point(x - o.x, y - o.y); }
      point<T> operator*(const T &k) const { return point(x * k, y * k); }
```

```
point<T> operator/(const T &k) const { return point(x / k, y / k); }
   T operator*(const point<T> &o) const { return x * o.y - y * o.x; }
   T operator&(const point<T> &o) const { return x * o.x + y * o.y; }
   void operator+=(const point<T> &o) { x += o.x; y += o.y; }
   void operator==(const point<T> &o) { x -= o.x; y -= o.y; }
   void operator*=(const T &k) { x *= k; y *= k; }
   void operator/=(const T &k) { x /= k; y /= k; }
   bool operator==(const point<T> &o) const { return x == o.x && y == o.y; }
   bool operator!=(const point<T> &o) const { return x != o.x || y != o.y; }
   db len() const { return sqrt(len2()); }//模长
   T len2() const { return x * x + y * y; }
};
const point<db> npos = point<db>(514e194, 9810e191), apos = point<db>(145e174, 999e180);
const int DS[4] = \{1, 2, 4, 3\};
tmpl int quad(const point<T> &o)//坐标轴归右上象限,返回值 [1,4]
   return DS[(sgn(o.y) < 0) * 2 + (sgn(o.x) < 0)];
tmpl bool angle_cmp(const point<T> &a, const point<T> &b)
   int c = quad(a), d = quad(b);
   if (c != d) return c < d;

### 7.6 分散层叠算法(Fractional Cascading)

 $O(n + q(k + \log n))$ , O(n)。 给出 k 个长度为 n 的有序数组。

现在有 q 个查询: 给出数 x,分别求出每个数组中大于等于 x 的最小的数 (非严格后继)。若后继不存在,则定义为 0。你需要在线地回答这些询问。

```
int a[M][N], b[M][N << 1], c[M][N << 1][2], len[M], ans[M];
int n, m, qs, p, q, d, i, j, x, y, la;
int main()
{
   cin >> n >> m >> qs >> d;
   for (j = 1; j \le m; j++) for (i = 0; i \le n; i++) cin >> a[j][i];
   for (j = 1; j \le m; j++) a[j][n] = inf + j; ++n;
   for (i = 0; i < n; i++) b[m][i] = a[m][i], c[m][i][0] = i;
   len[m] = n;
   for (j = m - 1; j; j--)
       p = 0, q = 1;
       while (p < n \&\& q < len[j + 1])
          if(a[j][p] < b[j + 1][q]) b[j][len[j]] = a[j][p], c[j][len[j]][0] = p++, c[j][len[j]]
              ]++][1] = q;
          else b[j][len[j]] = b[j + 1][q], c[j][len[j]][0] = p, c[j][len[j]++][1] = q, q += 2;
       while (p < n) b[j][len[j]] = a[j][p], c[j][len[j]][0] = p++, c[j][len[j]++][1] = q;
       while (q < len[j + 1]) b[j][len[j]] = b[j + 1][q], c[j][len[j]][0] = p, c[j][len[j]++][1]
           = q, q += 2;
   for (int ii = 1; ii <= qs; ii++)</pre>
       cin >> x; x ^= la;
       y = lower_bound(b[1], b[1] + len[1], x) - b[1];

       for (j = 2; j <= m; j++)
          if (y \&\& b[j][y - 1] >= x) --y;
          ans[j] = a[j][c[j][y][0]];//下标是c[j][y][0]
          y = c[j][y][1];
       }
       la = 0;
       for (i = 1; i <= m; i++) la ^= ans[i] > inf ? 0 : ans[i];
       if (ii % d == 0) printf("%d\n", la);
   }
}
```

## 7.7 圆上整点(二平方和定理)

```
x^2 + y^2 = n 的整数解的数目的四分之一 f(n) 是积性数论函数,且对于素数幂有: f(p^k) = \begin{cases} 1 & p = 2 \\ k+1 & p \equiv 1 \pmod 4 \\ (k+1) \mod 2 & p \equiv 3 \pmod 4 \end{cases}
```

以下代码给出所有的非负整数解。注意非负整数解个数不等于 f(n)。 时间复杂度为  $O(n^{\frac{1}{4}} + f(n))$ ,其中  $O(n^{\frac{1}{4}})$  是 pollard-rho 的复杂度。

f(n) 的量级不好分析,但不会超过约数个数  $O(d(n)) \approx O(n^{\frac{1}{3}})$ ,且可以推测不能达到。实践上  $10^{18}$  以内  $f(n) \leq 3072$ 。

```

       for(int i = 0;i < t;++i) _putchar(S[t - i - 1]);</pre>
       return *this;
   fast_iostream& operator << (char c){_putchar(c); return *this;}</pre>
   fast_iostream& operator << (const char *s){</pre>
       for(int i = 0;s[i];++i) _putchar(s[i]); return *this;
   }
```

|}fio;//unsigned

### 7.10 手动开栈

一种写法是文件开头放,但部分 OJ 会失效。

```
#pragma comment(linker, "/STACK:102400000,102400000")
```

另一种写法是在 main 开头写,但必须以 exit(0) 结束程序。 以下两个应该有一个是对的,不对会 CE。

```
{
   static int OP = 0;
   if (OP++ == 0)
   {
       int size = 256 << 20; // 256MB</pre>
       char *p = (char *)malloc(size) + size;
       _{asm}("movl_{\parallel}%0,_{\parallel}%%esp\n" :: "r"(p));
   }
}
{
   static int OP=0;
   if (OP++==0)
       int size=128<<20;//128MB</pre>
       char* p=new char[size]+size;
       __asm__ _volatile__("movqu%0,u%%rsp\n""pushqu$exit\n""jmpumain\n"::"r"(p));
   }
}
```

### 7.11 德扑

solve 返回按照出现次数排序的 vector<int> (0 下标处为牌型),这样就可以字典序比较了。

```
struct Q
{
   int suit, rank;
   bool operator<(const Q &o) const { return pair{rank, suit}<pair{o.rank, o.suit}; }</pre>
   bool operator==(const Q &o) const { return pair{rank, suit}==pair{o.rank, o.suit}; }
};
auto solve=[&](vector<Q> a)
   vector<int> res;
   vector<int> cnt(15);
   for (auto [s, r]:a) ++cnt[r];
   sort(all(a));
   int i;
   bool is_flush=1, is_str=0;
   for (i=1; i<5; i++) is_flush&=a[i].suit==a[0].suit;</pre>
   is_str=*max_element(all(cnt))==1&&a[0].rank+4==a[4].rank;
   vector<int> b(6);
   for (i=1; i<6; i++) b[i]=a[i-1].rank;</pre>
   sort(1+all(b), [&](int x, int y)
          return pair{cnt[x], x}>pair{cnt[y], y};
       });
```

```
if (b==vector{0, 12, 3, 2, 1, 0}) is_str=1, b[1]=0;
if (is_flush&&is_str) return b[0]=9, b;
if (cnt[b[1]]==4) return b[0]=8, b;
if (cnt[b[1]]==3&&cnt[b[4]]==2) return b[0]=7, b;
if (is_flush) return b[0]=6, b;
if (is_str) return b[0]=5, b;
if (cnt[b[1]]==3) return b[0]=4, b;
if (cnt[b[1]]==2&&cnt[b[3]]==2) return b[0]=3, b;
if (cnt[b[1]]==2) return b[0]=2, b;
return b;
};
auto turn=[&](string s)
{
   Q res=Q{"SHDC"s.find(s[0]), "23456789TJQKA"s.find(s[1])};
   return res;
};
```

# 7.14 公式

向上取整的整除分块  $[i, \lfloor \frac{n-1}{\lceil \frac{n}{i} \rceil - 1} \rfloor]$ 

n 个点 k 个连通块的生成树方案  $n^{k-2}\prod\limits_{i=1}^{k}siz_{i}$ 

(x,y) 曼哈顿距离  $\to (x+y,x-y)$  切比雪夫距离 (x,y) 切比雪夫距离  $\to (\frac{x+y}{2},\frac{x-y}{2})$  曼哈顿距离 Kummer's Theorem:  $\binom{n+m}{n}$  含 p  $(p \in \text{prime})$  的次数是 n+m 在 p 进制下的进位数

$$\ln(1 - x^V) = -\sum_{i \ge 1} \frac{x^{Vi}}{i}$$

$$x^{\bar{n}} = \sum_{i} S_1(n, i) x^i$$

$$\begin{cases} x \equiv a_1 \pmod{m_1} \\ x \equiv a_2 \pmod{m_2} \\ \cdots \end{cases}$$

$$\cdots$$

 $m_i$  为不同的质数。设  $M=\prod\limits_{i=1}^n m_i$ ,  $t_i imes rac{M}{m_i}\equiv 1\pmod{m_i}$ ,则  $x\equiv \sum\limits_{i=1}^n a_it_irac{M}{m_i}$ 。

V - E + F = 2,  $S = n + \frac{s}{2} - 1$ . (n 为内部, s 为边上)

用途:对于相邻的不相等的值,在中间画一条线(最外也画),连通块个数 = 1 + E - V +内部框个数

注意全都是不含矩形边界上的。

贝尔数(划分集合方案数)EGF:  $\exp(e^x-1)$ , $B_n = \sum_{i=0}^n S_2(n,i)$ ,伯努利数 EGF:  $\frac{x}{e^x-1}$ 

$$S_1(i,m) \text{ EGF: } \frac{(\sum\limits_{i\geq 0} \frac{x^i}{i})^m}{m!}, \ S_2(i,m) \text{ EGF: } \frac{(e^x-1)^m}{m!}$$

多项式牛顿迭代: 如果已知  $G(F(x)) \equiv 0 \pmod{x^{2n}}$ ,  $G(F_*(x)) \equiv 0 \pmod{x^n}$ , 则有  $F(x) \equiv 0$  $F_*(x) - \frac{G(F_*(x))}{G'(F_*(x))} \pmod{x^{2n}}$ 。求导时孤立的多项式视为常数。

$$\int_0^1 t^a (1-t)^b dt = \frac{a!b!}{(a+b+1)!}, \quad \sum_{i=0}^{n-1} i^{\underline{k}} = \frac{n^{\underline{k+1}}}{k+1}$$

Burnside 引理: 等价类数量为  $\sum_{g \in G} \frac{X^g}{|G|}$ ,  $X^g$  表示 g 变换下不动点的数量。

Polya 定理: 染色方案数为  $\sum_{g \in G} \frac{m^{c(g)}}{|G|}$ , 其中 c(g) 表示 g 变换下环的数量。

假设已经只保留了一个牛人酋长,其名字为  $A = a_1 a_2 \cdots a_l$ 。

假设王国旁边开了一座赌场,每单位时间(就称为"秒"吧)会有一个赌徒带着1铜币进入赌 场。

赌场规则很简单:支付x铜币赌下一秒会唱出y,如果猜对了就返还nx铜币,否则钱就没了。 每个赌徒会如下行动:支付 1 铜币赌下一秒会唱出  $a_1$ ,如果赌对了就支付得到的 n 铜币赌下 一秒会唱出  $a_2$ , 如果还对了就支付得到的  $n^2$  铜币赌下一秒会唱出  $a_3$ , 等等,以此类推,最后支付  $n^{l-1}$  铜币赌下一秒会唱出  $a_l$ 。

一旦连续唱出了  $a_1a_2\cdots a_l$ , 赌场老板就会认为自己亏大了而关门,并驱散所有赌徒。

那么关门前发生了什么呢?以  $A = \{1,4,1,5,1,1,4,1\}, n = 5$  为例:

- 最后一位赌徒拿着 5 铜币离开; - 倒数第三位赌徒拿着 53 铜币离开; - 倒数第八位赌徒拿着 58 铜币离开; - 其他所有赌徒空手而归。

我们可以发现 1,3 恰好是原序列的所有 border 的长度,而且对于其他的名字也有这样的规律。 这时候最神奇的一步来了:由于这个赌博游戏是公平的,因此赌场应该期望下不赚不赔,因此 关门时期望来了  $5+5^3+5^8$  个赌徒,因此期望需要  $5+5^3+5^8$  单位时间唱出这个名字。

同理,即可知道对于一般的 A,答案为:

$$\sum_{a_1 a_2 \cdots a_c = a_{l-c+1} a_{l-c+2} \cdots a_l} n^c$$

      cout<<"find\n";</pre>
   uniform_real_distribution<> a(1,2);
   numeric_limits<int>::max();
```

# 8.4 python 使用方法

注意事项: python 容易爆栈,且引用与赋值较为混乱。注意局部变量的 global 怎么写(如果需要修改全局内容)。

文件操作

```
fi = open("discuss.in", "r")
fo = open("discuss.out", "w")
n=int(fi.readline())
fo.write(str(ans))
```

类的构造, 重载运算符

```
class Q:
    def __init__(self,x,y):
        self.x=x
        self.y=y
    def __add__(self,o):
        r=Q(self.x+o.x,self.y+o.y)
```

8 语言基础 263

```
return r
   def __sub__(self,o):
       r=Q(self.x-o.x,self.y-o.y)
       return r
   def __mul__(self,o):
       return self.x*o.y-self.y*o.x
   def __lt__(self,o):
       if self.x!=o.x:
          return self.x<o.x</pre>
       return self.y<o.y</pre>
n,m=map(int,input().split())
c=list(map(int,input().split()))
print(*c)
a=Q(0,0)
b=Q(1,1)
if a<b-a:</pre>
   pass
```

### 9.9 毛毛虫剖分

毛毛虫剖分,一种由轻重链剖分(HLD)推广而成的树上结点重标号方法,支持修改 / 查询一只毛毛虫的信息,并且可以对毛毛虫的身体和足分别修改 / 查询不同信息.

严格强于树剖,而且复杂度和树剖一样哦!

一些定义 (默认在一棵树上):

毛毛虫: 一条链和与这条链邻接的所有结点构成的集合. 虫身(身体): 毛毛虫的链部分. 虫足(足): 毛毛虫除虫身的部分. 重标号方法首先重剖求出重链. DFS, 若现在处理到结点 u: 若 u 还未被标号,则为其标号. 若 u 是重链头,遍历这条重链,将邻接这条链的结点依次标号. 先递归重儿子,再递归轻儿子. 重标号性质对于重链,除链头外的结点标号连续. 对于任意结点,其轻儿子标号连续. 对于以重链头为根的子树,与这条重链邻接的所有结点标号连续. 这样就可以随便维护毛毛虫信息了,顺便还能维护链信息,子树信息等.

时间复杂度同轻重链剖分.

以 SAM 为例,若我们只保留所有的转移边 (u,v) ,满足到达 u 的路径数目大于到达 v 的路径数目一半,且从 v 出发的路径数目大于从 u 出发的路径数目一半,这样剩余的子图显然会形成若干条链,且每个点恰好在一条链上。这样,我们容易证明,从根结点出发的任何一条路径,至多经过  $O(\log n)$  条不在链上的转移边(也意味着至多经过  $O(\log n)$  条链)。

以下是一段示例代码,展示了将一条链对应区间取出来的过程

```
vector<int> e[N];
vector<pair<int, int>> seg[N], qu[N];
int ans[Q];
int dfn[N], dep[N], nfd[N], top[N], f[N], sz[N], hc[N], pre[N], fir[N], lst2[N], rt[N];
int
void insert()
void dfs1(int u)
{
    sz[u] = 1;
```

```
for (int v : e[u]) if (v != f[u])
       dep[v] = dep[u] + 1;
       f[v] = u;
       dfs1(v);
       sz[u] += sz[v];
       if (sz[v] > sz[hc[u]]) hc[u] = v;
   if (f[u]) erase(e[u], f[u]);
void dfs2(int u)
   static int id = 0;
   //dbg(u);
   if (!dfn[u])
       dfn[u] = ++id;
       nfd[id] = u;
   }
   if (top[u] == u)
