9 其他人的板子（补充）	279
9.1 最小树形图	279
9.2 MTT+exp	280
9.3 半平面交	283
9.4 多项式复合 (yurzhang)	284
9.5 下降幂多项式乘法	288
9.6 弦图找错	289
9.7 最长公共子序列	291
9.8 区间 LIS（排列）	293
9.9 区间 LCS	302

1 前言

此模板的初衷是个人使用，因此已有的模板可能未列出。建议结合 Heltion 模板和 HDU 模板使用。

模板需要的版本为 cpp17 或 cpp20。

大部分情况下，涉及取模的都需要使用 `unsigned long long`，即使类型名是 `ll`。这是因为值域较大有利于合理减少取模次数。目前，大部分都已经修改为 `ull`。

`optional` 的用法：一个 `optional` 变量 `r` 可以用 `if (r)` 判断其是否有值。取出值的方法是 `*r`。常见于包含无解又包含空集解的代码中，便于区分无解和空集解。

`rev` 宏通常用于数据结构中，正向信息是否与反向信息相同，若定义了宏则表示不同。例如矩阵乘法需要定义，而区间求和则不需要。定义后额外统计信息，会慢一点点。

常见的被漏掉的初始代码：

```
#define all(x) (x).begin(),(x).end()
template<class T1, class T2> bool cmin(T1 &x, const T2 &y) { if (y < x) { x = y; return 1; }
    return 0; }
template<class T1, class T2> bool cmax(T1 &x, const T2 &y) { if (x < y) { x = y; return 1; }
    return 0; }
```

常见的缺漏算法：

回文自动机。

2 数据结构

2.1 树状数组

支持单点修改、求前缀和、二分前缀和大于等于 x 的第一个位置。

```
template<class T> struct bit
{
    vector<T> a;
    int n;
    bit() { }
    bit(int nn) : n(nn), a(nn + 1) { }
    template<class TT> bit(int nn, TT *b) : n(nn), a(nn + 1)
    {
        for (int i = 1; i <= n; i++) a[i] = b[i];
        for (int i = 1; i <= n; i++) if (i + (i & -i) <= n) a[i + (i & -i)] += a[i];
    }
    void add(int x, T y)
    {
        //cerr<<"add "<<x<<" by "<<y<<endl;
        assert(1 <= x && x <= n);
        a[x] += y;
        while ((x += x & -x) <= n) a[x] += y;
    }
    T sum(int x)
    {
        //cerr<<"sum "<<x;
        assert(0 <= x && x <= n);
        T r = a[x];
        while (x ^= x & -x) r += a[x];
        //cerr<<"=" <<r<<endl;
        return r;
    }
    T sum(int x, int y)
    {
        return sum(y) - sum(x - 1);
    }
    int lower_bound(T x)
    {
        if (n == 0 || x <= 0) return 0;
        int i = __lg(n), j = 0;
        for (; i >= 0; i--) if ((1 << i | j) <= n && a[1 << i | j] < x) j |= 1 << i, x -= a[j];
        return j + 1;
    }
};
```

2.2 线段树

包含标记的线段树，支持线段树上二分，采用左闭右闭。但只支持求左侧第一个符合条件的下标。

要求：具有 `info+info`, `info+=tag`, `tag+=tag`。info, tag 需要有默认构造，但不必有正确的值。

示例的 tag 和 info 是区间加区间覆盖区间历史最大值。

对于线段树上二分，如果你要 check 的是前缀，可以在 false 时加入信息。

例如查找前缀和大于等于 s 的第一个下标，可以写成

```
[&](const int &x) {
    if (x >= s) return true;
    s -= x;
    return false; }
```

```
template<class info, class tag> struct sgt
{
    int n, shift;
    info *a;
    info tmp;
    vector<info> s;
    vector<tag> tg;
    vector<int> lz;
    bool flg;
    void build(int x, int l, int r)
    {
        if (l == r)
        {
            s[x] = (flg ? tmp : a[l]);
            return;
        }
        int c = x * 2, m = l + r >> 1;
        build(c, l, m); build(c + 1, m + 1, r);
        s[x] = s[c] + s[c + 1];
    }
    sgt(info *b, int L, int R) : n(R - L + 1), shift(L - 1), a(b + L - 1), s(R - L + 1 << 2), tg(R - L + 1 << 2), lz(R - L + 1 << 2)
    {
        flg = 0;
        build(1, 1, n);
    } // [L,R]
    sgt(info b, int L, int R) : n(R - L + 1), shift(L - 1), s(R - L + 1 << 2), tg(R - L + 1 << 2), lz(R - L + 1 << 2)
    {
        tmp = b;
        flg = 1;
        build(1, 1, n);
    } // [L,R]
    int z, y;
    info res;
    tag dt;
    bool fir;

};

```

2.3 珂朵莉树

支持区间赋值、单点访问。维护每个连续段的范围和值。

如果希望维护所有连续段的整体信息（如长度的最大值），修改 `add` 和 `del` 函数即可，分别表示连续段被加入和被删去。

特别注意一开始 `insert` 的不会触发 `add`，只有 `modify` 会触发。

```

namespace chtholly_tree
{
    using T = int; // 可以把 T 修改为任意想要的类型。
    struct node
    {
        int l;
        mutable int r;
        mutable T v;
        int len() const { return r - l + 1; }
        bool operator<(const node &x) const { return l < x.l; }
    };
    void add(const node &a) { }
    void del(const node &a) { }
    class odt : public set<node>
    {
    public:
        typedef odt::iterator iter;
        iter split(int x)

```

```

{
    iter it = lower_bound({x});
    if (it != end() && it->l == x) return it;
    node t = *--it, a = {t.l, x - 1, t.v}, b = {x, t.r, t.v};
    del(*it); add(a); add(b);
    erase(it); insert(a);
    return insert(b).first;
}

iter modify(int l, int r, T v)//[l,r]
{
    iter lt, rt, it;
    rt = r == rbegin()->r ? end() : split(r + 1); lt = split(l);//[lt,rt)
    while (lt != begin() && (it = prev(lt))->v == v) l = (lt = it)->l;
    while (rt != end() && rt->v == v) r = (rt++)->r;
    for (it = lt; it != rt; it++) del(*it);
    add({l, r, v});
    erase(lt, rt);
    return insert({l, r, v}).first;
}

T operator[](const int x) const { return prev(upper_bound({x}))->v; }//直接访问单点
iter find(int x) const { return prev(upper_bound({x})); }//找到对应的线段
};
}

using chtholly_tree::node, chtholly_tree::odt;
typedef odt::iterator iter;
int main()
{
    odt s;
    s.insert({0, 5, 1});    // 先 insert({L,R,x}) 表示整个下标范围和初始值。 左闭右闭。
                           // s={1,1,1,1,1,1}
    s.modify(2, 3, 2);      // 左闭右闭。s={1,1,2,2,1,1}
    for (auto [l, r, v] : s)
    {
        //(l,r,v)=(0,1,1)
        //(l,r,v)=(2,3,2)
        //(l,r,v)=(4,5,1)
    }
}

```

2.4 带删堆

本质是额外维护一个堆 q 表示要被删除的元素，当 p 的最值和 q 一样时删除。

需要保证每次 pop 的元素都存在于堆中。

本代码的用法和 `priority_queue` 一致。

```

template<class T, class T1 = vector<T>, class T2 = less<T>> struct heap
{
private:
    priority_queue<T, T1, T2> p, q;
public:
    void push(const T &x)
    {
        if (!q.empty() && q.top() == x)
        {
            q.pop();
            while (!q.empty() && q.top() == p.top()) p.pop(), q.pop();
        }
    }
};

```

```

    }
    else p.push(x);
}
void pop()
{
    p.pop();
    while (!q.empty() && p.top() == q.top()) p.pop(), q.pop();
}
void pop(const T &x)
{
    if (p.top() == x)
    {
        p.pop();
        while (!q.empty() && p.top() == q.top()) p.pop(), q.pop();
    }
    else q.push(x);
}
T top() const { return p.top(); }
int size() const { return p.size() - q.size(); }
bool empty() const { return p.empty(); }
vector<T> to_vector() const
{
    vector<T> a;
    auto P = p, Q = q;
    while (P.size())
    {
        a.push_back(P.top()); P.pop();
        while (Q.size() && P.top() == Q.top()) P.pop(), Q.pop();
    }
    return a;
}
};

```

2.5 前 k 大的和

本质是用小根堆维护前 k 大的数，用大根堆维护其余数。

如果需要支持删除，结合前面一个使用，或者直接用 `multiset` 进行 `extract`。

为了方便起见，直接给出支持删除的版本，并且使用 `long long`。如果不需要支持删除，类型改为优先队列并去掉 `pop` 函数即可。

注意：复杂度为 $O(|k - k'|)$ ，其中 k' 是上一次询问的 k 。也就是说，多组询问时询问的 k 的差值应该尽可能小。

其用法与 `priority_queue` 保持一致，可以用同样的方法改写成前 k 小。

```

using ll = long long;
template<class T, class T1 = vector<T>, class T2 = less<T>> struct ksum_pop
{
private:
    struct __cmp
    {
        bool operator()(const T &x, const T &y) const
        {
            return x != y && !T2()(x, y);
        }
    };
};
heap<T, T1, __cmp> p;

```

```

    heap<T, T1, T2> q;
    ll cur;
public:
    ksum_pop() : cur(0) { }
    void push(const T &x)
    {
        if (!q.size() || !T2()(x, q.top())) p.push(x), cur += x; else q.push(x);
    }
    int size() const { return p.size() + q.size(); }
    void pop(const T &x)
    {
        if (q.size() && !T2()(q.top(), x)) q.pop(x);
        else p.pop(x), cur -= x;
    }
    ll sum(int k)
    {
        while (p.size() < k)
        {
            cur += q.top();
            p.push(q.top());
            q.pop();
        }
        while (p.size() > k)
        {
            cur -= p.top();
            q.push(p.top());
            p.pop();
        }
        return cur;
    }
};

```

2.6 左偏树/可并堆

建议不要使用。pb_ds 可以替代这个功能。我完全没有使用过这个板子。

$O((n+q)\log n)$, $O(n)$ 。

```

struct left_tree//小根堆，大根堆需要改的地方注释了
{
    int j1[N],v[N],f[N],c[N][2],tf[N],n; //tf只有删非堆顶才用
    bool ed[N];
    void init(const int nn,const int *a)
    {
        j1[0]=-1;n=nn;
        memset(j1+1,0,n<<2);
        memset(tf+1,0,n<<2); //同上
        memset(c+1,0,n<<3);
        memset(ed+1,0,n);
        for (int i=1;i<=n;i++) v[f[i]=i]=a[i];
    }
    int mg(int x,int y)
    {
        if (!(x&& y)) return x|y;
        if (v[x]>v[y] || v[x]==v[y]&&x>y) swap(x,y); //改
        tf[c[x][1]=mg(c[x][1],y)]=x; //同上
        if (j1[c[x][0]]<j1[c[x][1]]) swap(c[x][0],c[x][1]);
    }
};

```

```

        jl[x]=jl[c[x][1]]+1;
        return x;
    }
    int getf(int x)
    {
        if (f[x]==x) return x;
        return f[x]=getf(f[x]);
    }
    int merge(int x,int y)
    {
        if (ed[x]||ed[y]||(x=getf(x))== (y=getf(y))) return x;
        int z=mg(x,y);return f[x]=f[y]=z;
    }
    int getv(int x)//需要自行判断是否存在
    {
        return v[getf(x)];
    }
    int del(int x)//删除堆内最值
    {
        tf[c[x][0]]=tf[c[x][1]]=0;
        f[c[x][0]]=f[c[x][1]]=f[x]=mg(c[x][0],c[x][1]);
        ed[x]=1;c[x][0]=c[x][1]=tf[x]=0;return f[x];
    }
    int del_all(int x)//删除堆内非最值 (没验证过)
    {
        int fa=tf[x];
        if (f[c[x][0]]==x) f[c[x][0]]=getf(tf[x]);
        if (f[c[x][1]]==x) f[c[x][1]]=f[tf[x]];
        tf[x]=tf[c[x][0]]=tf[c[x][1]]=0;
        tf[c[fa][c[fa][1]]==x]=mg(c[x][0],c[x][1])=fa;
        c[x][0]=c[x][1]=0;
        while (jl[c[fa][0]]<jl[c[fa][1]])
        {
            swap(c[fa][0],c[fa][1]);
            jl[fa]=jl[c[fa][1]]+1;
            fa=tf[fa];
        }
    }
    void out(int n)
    {
        for (int i=1;i<=n;i++) printf("%d: %c%d&%d %f%d %v\n",i,c[i][0],c[i][1],f[i],v[i]);
    }
};

```

2.7 树状数组区间加区间求和

本质： a_n 区间加等价于差分数组 d_n 的单点加。

$$\sum_{i=1}^m a_i = \sum_{i=1}^m \sum_{j=1}^i d_j = \sum_{j=1}^m d_j (m-j+1) = ((m+1) \sum_{j=1}^m d_j) - (\sum_{j=1}^m j d_j)。$$

分别维护 d_j 和 $j d_j$ 的前缀和。

$O(n) \sim O(q \log n)$, $O(n)$ 。

```

template<class T> struct bit
{
    vector<T> a, b;

```

```

int n;
template<class TT> bit(int n, TT *c) :n(n), a(n + 1), b(n + 1)
{
    for (int i = 1; i <= n; i++) b[i] = -c[i];
    for (int i = 1; i <= n; i++) if (i + (i & -i) <= n) b[i + (i & -i)] += b[i];
}
void add(int l, int r, T d)
{
    T x;
    int i;
    for (i = l, x = d * i; i <= n; i += i & -i) a[i] += d, b[i] += x;
    for (i = r + 1, x = d * i; i <= n; i += i & -i) a[i] -= d, b[i] -= x;
}
void add(int x, T d)
{
    for (int i = x; i <= n; i += i & -i) b[i] -= d;
}
T sum(int x)
{
    T r1 = 0, r2 = 0;
    for (int i = x; i; i ^= i & -i) r1 += a[i], r2 += b[i];
    return r1 * (x + 1) - r2;
}
T sum(int l, int r)
{
    return sum(r) - sum(l - 1);
}
};

```

2.8 二维树状数组矩形加矩形求和

本质还是差分，只不过这次要维护 $d_{i,j}, d_{i,j}i, d_{i,j}j, d_{i,j}ij$ 。

$O(n^2 + q \log^2 n)$, $O(n^2)$

```

template <class T> struct bit
{
    int n, m;
    vector<vector<T>> a, b, c, d;
private:
    void modify(vector<vector<T>> &a, int x, int y, T z)
    {
        for (int i = x; i <= n; i += i & -i) for (int j = y; j <= m; j += j & -j) a[i][j] += z;
    }
    T ask(const vector<vector<T>> &a, int x, int y) const
    {
        T res = 0; --x; --y;
        for (int i = x; i; i ^= i & -i) for (int j = y; j; j ^= j & -j) res += a[i][j];
        return res;
    }
    void cg(int x, int y, T t)
    {
        if (x > n || y > n) return;
        modify(a, x, y, t);
        modify(b, x, y, x * t);
        modify(c, x, y, y * t);
        modify(d, x, y, x * y * t);
    }
};

```

```

    }
public:
    bit(int n, int m) : n(n), m(m), a(n + 1, vector<T>(m + 1)), b(a), c(a), d(a) { }
    void add(int x1, int y1, int x2, int y2, T t)
    {
        ++x2, ++y2;
        cg(x1, y1, t); cg(x2, y2, t);
        cg(x1, y2, -t); cg(x2, y1, -t);
    }
    T sum(int x, int y) const
    {
        if (x <= 0 || y <= 0) return 0;
        ++x; ++y;
        return ask(a, x, y) * x * y + ask(d, x, y) - ask(b, x, y) * y - ask(c, x, y) * x;
    }
    T sum(int x1, int y1, int x2, int y2) const
    {
        --x1; --y1;
        return sum(x2, y2) + sum(x1, y1) - sum(x2, y1) - sum(x1, y2);
    }
};

```

2.9 带修莫队

按照 $n^{\frac{2}{3}}$ 分块，排序关键字是 l, r, t 所在的块 (t 是版本号，每次修改都会增加一个版本)，可以奇偶分块优化。

相比于传统莫队多了一个 modify。这里只给出参考代码，功能是带修区间数颜色。

$O(n^{\frac{5}{3}})$, $O(n)$ 。

```

#include "bits/stdc++.h"
using namespace std;
typedef long long ll;
#define all(x) (x).begin(), (x).end()
const int N=1.4e5, M=1e6+2;
int a[N], ans[N], bel[N], cnt[M], sum, z, y, cur;
struct P
{
    int p, v;
};
struct Q
{
    int l, r, t, p;
    bool operator<(const Q &o) const
    {
        if (bel[l] != bel[o.l]) return bel[l] < bel[o.l];
        if (bel[r] != bel[o.r]) return (bel[l] & 1) ^ bel[r] < bel[o.r];
        return (bel[r] & 1) ? t < o.t : t > o.t;
    }
};
Q b[N];
P d[N];
void add(const int &x) {sum += !(cnt[a[x]]++);}
void del(const int &x) {sum -= !(--cnt[a[x]]);}
void mdf(const int &x)
{
    auto &[p, v] = d[x];

```

```

    if (z<=p&& p<=y) del(p);
    swap(a[p],v);
    if (z<=p&& p<=y) add(p);
}
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    int n,m,q1=0,q2=0,i,ksiz;
    cin>>n>>m;
    for (i=1;i<=n;i++) cin>>a[i];
    for (i=1;i<=m;i++)
    {
        char c;
        int l,r;
        cin>>c>>l>>r;
        if (c=='Q') ++q1,b[q1]={l,r,q2,q1};
        else d[++q2]={l,r};
    }
    ksiz=max(1.0,round(cbrt((1ll)n*n)));
    for (i=1;i<=n;i++) bel[i]=i/ksiz;
    sort(b+1,b+q1+1);
    z=b[1].l;y=z-1;cur=0;
    for (i=1;i<=q1;i++)
    {
        auto [l,r,t,p]=b[i];
        while (z>l) add(--z);
        while (y<r) add(++y);
        while (z<l) del(z++);
        while (y>r) del(y--);
        while (cur<t) mdf(++cur);
        while (cur>t) mdf(cur--);
        ans[p]=sum;
    }
    for (i=1;i<=q1;i++) cout<<ans[i]<<'\\n';
}

```

2.10 二次离线莫队

直接摘录题解，用途不大。

$O(n\sqrt{n})$, $O(n)$ 。

珂朵莉给了你一个序列 a ，每次查询给一个区间 $[l, r]$ ，查询 $l \leq i < j \leq r$ ，且 $a_i \oplus a_j$ 的二进制表示下有 k 个 1 的二元组 (i, j) 的个数。 $\oplus$ 是指按位异或。

二次离线莫队，通过扫描线，再次将更新答案的过程离线处理，降低时间复杂度。假设更新答案的复杂度为 $O(k)$ ，它将莫队的复杂度从 $O(nk\sqrt{n})$ 降到了 $O(nk + n\sqrt{n})$ ，大大简化了计算。设 x 对区间 $[l, r]$ 的贡献为 $f(x, [l, r])$ ，我们考虑区间端点变化对答案的影响：以 $[l..r]$ 变成 $[l..(r+k)]$ 为例， $\forall x \in [r+1, r+k]$ 求 $f(x, [l, x-1])$ 。我们可以进行差分： $f(x, [l, x-1]) = f(x, [1, x-1]) - f(x, [1, l-1])$ ，这样转化为了一个数对一个前缀的贡献。保存下来所有这样的询问，从左到右扫描数组计算就可以了。但是这样做，空间是 $O(n\sqrt{n})$ 的，不太优秀，而且时间常数巨大。。这样的贡献分为两类：

1. 减号左边的贡献永远是一个前缀和它后面一个数的贡献。这可以预处理出来。2. 减号右边的贡献对于一次移动中所有的 x 来说，都是不变的。我们打标记的时候，可以只标记左右端点。

这样，减小时间常数的同时，空间降为了 $O(n)$ 级别。是一个很优秀的算法了。处理前缀询问的时候，我们利用异或运算的交换律，即 $a \text{ xor } b = c \iff a \text{ xor } c = b$ 开一个桶 t ， $t[i]$ 表示当前前缀中与 i 异或有 k 个数位为 1 的数有多少个。则每加入一个数 $a[i]$ ，对于所有 $\text{popcount}(x) = k$ 的

x , $t[a[i] \text{ xor } x] \leftarrow t[a[i] \text{ xor } x] + 1$ 即可。

```
typedef long long ll;
const int N = 1e5 + 2, M = 1 << 14;
ll f[N], ans[N], ta[N];
int a[N], cnt[M], bel[N], pc[M], st[N];
int n, m, ksiz;
struct Q
{
    int z, y, wz;
    bool operator<(const Q &x) const { return (bel[z] < bel[x.z]) || (bel[z] == bel[x.z]) && ((y < x.y) && (bel[z] & 1) || (y > x.y) && (1 ^ bel[z] & 1)); }
};
Q mq(const int x, const int y, const int z)
{
    Q a;
    a.z = x; a.y = y; a.wz = z;
    return a;
}
Q q[N];
vector<Q> b[N];
int main()
{
    ios::sync_with_stdio(false);
    cin.tie(0);
    int i, j, k, l = 1, r = 0, tp = 0, x, na;
    cin >> n >> m >> k; ksiz = sqrt(n);
    for (i = 1; i <= n; i++) { cin >> a[i]; bel[i] = (i - 1) / ksiz + 1; }
    if (k == 0) st[++tp] = 0;
    for (i = 1; i < 16384; i++)
    {
        if (i & 1) pc[i] = pc[i >> 1] + 1; else pc[i] = pc[i >> 1];
        if (pc[i] == k) st[++tp] = i;
    }
    for (i = 1; i <= n; i++)
    {
        j = tp + 1; f[i] = f[i - 1];
        while (--j) f[i] += cnt[st[j] ^ a[i]];
        ++cnt[a[i]];
    }
    for (i = 1; i <= m; i++) { cin >> q[i].z >> q[q[i].wz = i].y; }
    sort(q + 1, q + m + 1);
    for (i = 1; i <= m; i++)
    {
        ans[i] = f[q[i].y] - f[r] + f[q[i].z - 1] - f[l - 1];
        if (k == 0) ans[i] += q[i].z - 1;
        if (r < q[i].y)
        {
            b[l - 1].push_back(mq(r + 1, q[i].y, -i));
            r = q[i].y;
        }
        if (l > q[i].z)
        {
            b[r].push_back(mq(q[i].z, l - 1, i));
            l = q[i].z;
        }
        if (r > q[i].y)
        {

```

```

        b[l - 1].push_back(mq(q[i].y + 1, r, i));
        r = q[i].y;
    }
    if (l < q[i].z)
    {
        b[r].push_back(mq(l, q[i].z - 1, -i));
        l = q[i].z;
    }
}
memset(cnt, 0, sizeof(cnt));
for (i = 1; i <= n; i++)
{
    j = tp + 1; x = a[i];
    while (--j) ++cnt[x ^ st[j]];
    for (j = 0; j < b[i].size(); j++)
    {
        na = 0; l = b[i][j].z; r = b[i][j].y;
        for (k = l; k <= r; k++) na += cnt[a[k]];
        if (b[i][j].wz > 0) ans[b[i][j].wz] += na; else ans[-b[i][j].wz] -= na;
    }
}
for (i = 2; i <= m; i++) ans[i] += ans[i - 1];
for (i = 1; i <= m; i++) ta[q[i].wz] = ans[i];
for (i = 1; i <= m; i++) printf("%lld\n", ta[i]);
}

```

2.11 回滚莫队

不删除的莫队，比如求 $\max$ 。

做法：块内询问暴力。对于 l 所在块相同的询问，按照 r 升序排序，并且将左指针固定在 l 所在块的最右侧。（由于块内询问暴力，这不会导致左指针更大）

回答每个询问的时候，先右端点右移到 r ，然后左端点左移到 l 。询问完成后，把左端点移回去。移回去的过程虽然涉及删除，但不需要维护答案变成什么了（因为在左端点左移之前已经求过了）。换句话说，相当于“撤销”而不是删除，完全可以记录移动过程中的所有变化来撤销。

$O(n\sqrt{n})$, $O(n)$ 。

```

#include "bits/stdc++.h"
using namespace std;
const int N = 2e5 + 2;
int a[N], z[N], y[N], wz[N], b[N], d[N], bel[N], ans[N], st[N][2], pos[N][2];
void qs(int l, int r)
{
    int i = l, j = r, m = bel[z[l + r >> 1]], mm = y[l + r >> 1];
    while (i <= j)
    {
        while ((bel[z[i]] < m) || (bel[z[i]] == m) && (y[i] < mm)) ++i;
        while ((bel[z[j]] > m) || (bel[z[j]] == m) && (y[j] > mm)) --j;
        if (i <= j)
        {
            swap(wz[i], wz[j]);
            swap(z[i], z[j]);
            swap(y[i++], y[j--]);
        }
    }
}
if (i < r) qs(i, r);

```

```

    if (l < j) qs(l, j);
}
int main()
{
    ios::sync_with_stdio(false);
    cin.tie(0);
    cin >> n;
    ksiz = sqrt(n);
    for (i = 1; i <= n; i++) { cin >> a[i]; b[i] = a[i]; bel[i] = (i - 1) / ksiz + 1; }
    sort(b + 1, b + n + 1);
    d[gs = 1] = b[1];
    for (i = 2; i <= n; i++) if (b[i] != b[i - 1]) d[++gs] = b[i];

2.12 李超树

题意：插入线段，查询某个 x 的最大 y （输出最小编号）

算法核心：修改时，线段树每个点只维护在中点取值最大的线段，中点取值较小的线段只会至多一侧有用，递归下去插入，复杂度 $O(\log^2)$ 。查询时询问线段树上 $\log$ 个点的线段中最大的。

```

2.19 Segmenttree Beats!

核心是 P (tag) 和 Q (info) 的维护。线段树部分是套的模板，并非全都有用。

1. l, r, k : 对于所有的 $i \in [l, r]$, 将 A_i 加上 k (k 可以为负数)。

2. l, r, v : 对于所有的 $i \in [l, r]$, 将 A_i 变成 $\min(A_i, v)$ 。
3. l, r : 求 $\sum_{i=l}^r A_i$ 。
4. l, r : 对于所有的 $i \in [l, r]$, 求 A_i 的最大值。
5. l, r : 对于所有的 $i \in [l, r]$, 求 B_i 的最大值。

其中 B_i 是 A_i 的历史最大值。

```

```

2.26 表达式树

传入表达式，输出表达式树。

输入的第二个参数是全体括号以外的运算符，每个运算符要记录字符优先级和是否右结合。优先级数字越大，越优先计算，且优先级必须为正整数。

输出的第一个参数是子结点数组，第二个参数是每个结点对应的字符，第三个参数是根。结点编号从 1 开始。

输出的表达式树满足每个结点对应一个字符。若包含数字串，则视为相邻数码之间加一个井号，表示“数码链接”这个运算符。你不需要，也不应该手动加入这个井号。

如果表达式非法，将返回根为 0。不允许一元运算符（负号），不允许省略乘号，不允许出现字母（除非字母是运算符）。

如果需要支持字母作为数字，修改所有包含 `isdigit` 的部分。

由于存在“数码链接”，在 `dfs` 树的时候最好记录一下子树大小，便于链接时计算（你不能在链接时直接看右子树的数字大小，因为有可能有前导 0）。

```

2.27 区间排序区间复合

时空 $O((n + m) \log V)$ ，其中 V 是排序关键字的值域，要求排序关键字唯一。实际效率较低， 10^5 要 1.2s。

构造函数传入排序关键字与信息，以及排序关键字的值域范围。

与其他板子不同的是，所有区间都是左闭右开的，下标从 0 开始。

```

3.4 扩展欧拉定理

求 $a \uparrow\uparrow b \bmod c$ 。前面的 Prime 命名空间只是求 φ 用的。

特别注意，这里的 i64 不是无符号。

```

namespace Prime
{
    using ui = unsigned;
    const int N = 1e6 + 2;
    const auto M = (N - 1ll) * (N - 1);
    ui pr[N], mn[N], phi[N], cnt;
    int mu[N];
    void init_prime()
    {
        ui i, j, k;
        phi[1] = mu[1] = 1;
        for (i = 2; i < N; i++)
        {
            if (!mn[i])
            {
                pr[cnt++] = i;
                phi[i] = i - 1; mu[i] = -1;
                mn[i] = i;
            }
            for (j = 0; (k = i * pr[j]) < N; j++)
            {
                mn[k] = pr[j];
                if (i % pr[j] == 0)
                {
                    phi[k] = phi[i] * pr[j];
                    break;
                }
                phi[k] = phi[i] * (pr[j] - 1);
                mu[k] = -mu[i];
            }
        }
        //for (i=2;i<N;i++) if (mu[i]<0) mu[i]+=p;
    }
    template<typename T> T getphi(T x)

```

```

    }
};

```

3.5 exgcd

$O(\log p)$, $O(\log p)$ 。

递归版：

```

int exgcd(int a, int b, int c)//ax+by=c,return x
{
    if (a == 0) return c / b;
    return (c - (ll)b * exgcd(b % a, a, c)) / a % b;
}

```

递推版：

```

pair<ll, ll> exgcd(ll a, ll b, ll c)//ax+by=c, {-1,-1} 无解, b=0 返回 {c/a,0}, 否则返回最小非负 x
{
    assert(a || b);
    ll d = gcd(a, b);
    if (c % d) return {-1, -1};
    if (!b) return {c / a, 0};
    if (a < 0) a = -a, b = -b, c = -c;
    ll x = 1, x1 = 0, p = a, q = b, k;

```

```

b = abs(b);
while (b)
{
    k = a / b;
    x -= k * x1; a -= k * b;
    swap(x, x1);
    swap(a, b);
}
b = abs(q / d);
x = (c / d) % b * (x % b) % b;
if (x < 0) x += b;
return {x, (ll)((c - (ll)p * x) / q)};
}
ll fun(ll a, ll b, ll p)//ax=b(mod p)
{
    return exgcd(a, -p, b).first % p;
}

```

3.6 exCRT

CRT: 设 $M = \prod_{i=1}^n m_i$, $t_i \times \frac{M}{m_i} \equiv 1 \pmod{m_i}$, 则 $x \equiv \sum_{i=1}^n a_i t_i \frac{M}{m_i}$ 。

以下为 exCRT, 与 CRT 无关。实现了一个类 Q, 表示一条方程, 支持合并。

```

namespace CRT
{
    pair<ll, ll> exgcd(ll a, ll b, ll c)
    {
        assert(a || b);
        ll d = gcd(a, b);
        if (c % d) return {-1, -1};
        if (!b) return {c / a, 0};
        if (a < 0) a = -a, b = -b, c = -c;
        ll x = 1, x1 = 0, p = a, q = b, k;
        b = abs(b);
        while (b)
        {
            k = a / b;
            x -= k * x1; a -= k * b;
            swap(x, x1);
            swap(a, b);
        }
        b = abs(q / d);
        x = x * (c / d) % b;
        if (x < 0) x += b;
        return {x, (c - p * x) / q};
    }
    struct Q
    {
        ll p, r;//0<=r<p
        Q operator+(const Q &o) const
        {
            if (p == 0 || o.p == 0) return {0, 0};
            auto [x, y] = exgcd(p, -o.p, r - o.r);
            if (x == -1 && y == -1) return {0, 0};
            ll q = lcm(p, o.p);
            return {q, ((r - x * p) % q + q) % q};
        }
    };
}

```

```

    }
};
}
using CRT::Q;

```

3.7 exBSGS

$O(\sqrt{n})$ 。哈希表 ht 可以用 map 代替。

```

namespace BSGS

3.9 杜教筛

求 $\varphi(n)$ 的前缀和。

核心：构造 g 满足 $h(n) = \sum_{d|n} f(d)g(\frac{n}{d})$ 容易计算，

则有 $\sum_{i=1}^n h(i) = \sum_{i=1}^n g(i) \sum_{j=1}^{\lfloor n/i \rfloor} f(j)$,

故 $g(1) \sum_{j=1}^n f(j) = \sum_{i=1}^n h(i) - \sum_{i=2}^n g(i) \sum_{j=1}^{\lfloor n/i \rfloor} f(j)$,

则 f 前缀和可以递归求解。

```

namespace du_seive
{
    typedef unsigned int ui;
    typedef unsigned long long ull;
    unordered_map<ull, ui> mp;
    const int N = 1e7 + 2;

}

```

3.13 原根

你应该传入的是模数 m 和你提供的 `getw` 函数，用于分解质因数。

以下以我的 pollard rho 模板为例。如果在现场赛且范围不大，手动求出更为方便。

定理：只有 $2, 4, p^k, 2p^k$ 有原根。因此可以优化到只分解一次，但没必要。

```
namespace get_root
{
    using ull = unsigned long long;
    using u128 = __uint128_t;
    ull ksm(ull x, ull y, ull p)
    {
        ull r = 1;
        while (y)
        {
            if (y & 1) r = (u128)r * x % p;
            x = (u128)x * x % p; y >>= 1;
        }
        return r;
    }
    template<class T> ll getrt(ull m, T getw)
    {
        assert(m);
        if (m <= 4) return (ll)m - 1;
        ull phi = m;
        auto w = getw(m);
        if (w.size() >= 3 || m % 4 == 0 || w.size() == 2 && w[0] != 2) return -1;
        for (ull x : w) phi = phi / x * (x - 1);
        w = getw(phi);
        for (ull &x : w) x = phi / x;
        for (ull i = 2; i < m; i++) if (gcd(i, m) == 1)
        {
            for (ull x : w) if (ksm(i, x, m) == 1) goto no;
            return i;
        }
        no::;
    }
    return -1;
}

using get_root::getrt;
int main()
{
    ios::sync_with_stdio(0); cin.tie(0);
    cout << fixed << setprecision(15);
    ull p;
    cin >> p;
    cout << getrt(p, [&](ull m) {
        auto ww = pr::getw(m);
        vector<ull> w;
        for (auto [p, k] : ww) w.push_back(p);
        return w;
    }) << '\n';
}
```

3.24 NTT

一种较快的 NTT（尤其是对于卷积以外的用途），但不推荐在不熟悉的情况下直接使用。一般的卷积可以参照字符串部分通配符的字符串匹配，其余的用途可以参照其他板子。

如果确实需要卡常，建议先抄写需要的函数，并递归地找到需要补的内容。

注意事项：所有 ull 为无符号。始终保证数组大小为 2^n ，不应当使用 `resize` 而应该使用取模来调整长度。三种卷积对应的运算符见注释。

需要特别小心其长度的变化，注意不要越界。如果修改模数，`dft` 和 `hf_dft` 处有一个参数也要修改。

常见函数如下（带 `new` 的基本上都是较快但较长的）：

卷积 `operator*`，循环卷积 `operator&`，差卷积 `operator^`，求逆 `operator~` / （包含一个较短版，被注释了），分治 `cdq`，对数 `ln`，指数 `exp`, `exp_cdq`, `exp_new`，开方 `sqrt`, `sqrt_new`，幂函数 `pow(Q, ull)`, `pow(Q, string)`, `pow2(Q, ull)`, `pow(Q, ull, Q)`，整除与取模 `div`, `mod`, `div_mod`，线性递推 `recurrent`, `recurrent_new`, `recurrent_interval`，连乘 `prod`, `prod_new`，多点求值 `evaluation`, `evaluation_new`，阶乘 `factorial`，快速插值 `interpolation`，复合（逆）`comp`, `comp_inv`，多项式平移 `shift`，区间点值平移 `shift`，Z 变换 `czt`，贝尔数（ $[n]$ 划分等价类方案数）`Bell`，斯特林数 `S1_row`, `S1_column`, `S2_row`, `S2_column`, `signed_S1_row`，伯努利数 `Bernoulli`，划分数 `Partition`，最大公因式 `gcd`，求根 `root`，模多项式意义的逆 `inverse`，转牛顿级数 `poly_to_newton`, `poly_to_facpow`, `newton_to_poly`, `facpow_to_poly`，下降幂乘法 `mul_facpow`。

3.28 万能欧几里得/min of mod of linear

题意: $\sum_{x=0}^{n-1} \lfloor \frac{ax+b}{m} \rfloor \quad (0 \leq a, b < m)$

原理：考虑紧贴着斜线的折线的答案。每个 `nd` 表示的是一段折线，你需要实现 `operator+` 来计算出拼接两个折线之后的答案。注意，需要实现默认构造。

你需要传入的 `dx` 和 `dy` 表示向上和向右的折线的答案（也就是边界）。图中对应的折线为 `RURRRRURRRRR`。

以对 x 求和为例，通常的处理手段是在 `dx` 时计算 $x = 1$ 的答案，在 `dy` 时更新辅助数组。

注意，如果 $x = 0$ 处有答案，你需要手动计算它，并保证传入的 $b < m$ 。

如果这段向上的竖线对后面有影响，你可以在一开始先加一个 `ksm(dy, ...)`，但你仍然可能需要手动计算 $x = 0$ 。

如果答案要取模，特别注意 y 有可能比模数大！不卡时间请使用 `int128`。

```
struct nd
{
    ll x, y, sy;
    nd operator+(const nd &o) const
    {
        return {x + o.x, y + o.y, sy + o.sy + y * o.x};
    }
};
nd ksm(nd a, ll k)
{
    nd res{ };
    while (k)
    {
        if (k & 1) res = res + a;
        a = a + a; k >>= 1;
    }
    return res;
}
```

```

}

4 字符串

4.1 字典树 (trie 树)

```

struct trie
{
    const static int N = 1e6 + 2, M = 52;
    int c[N][M], sz[N]; //sz 维护有多少个以当前字符串为前缀的字符串。
    int cnt = 1;
    void insert(string s)
    {
        int u = 1;
        ++sz[u];
        for (char ch : s)
        {
            assert(ch >= 0 && ch < M);
            int &v = c[u][ch];
            if (!v) v = ++cnt;
            u = v;
            ++sz[u];
        }
        //此时 u 是字符串结束位置。你可以在此存储结点信息。
    }
    int match(string s) //返回字符串结束位置。可能为 0。
    {
        int u = 1;
        for (char ch : s)
        {
            assert(ch >= 0 && ch < M);
            u = c[u][ch];
            if (!u) return 0;
        }
        return u;
    }
    void clear()
    {
        memset(c, 0, (cnt + 1) * sizeof c[0]);
        memset(sz, 0, (cnt + 1) * sizeof sz[0]);
        cnt = 1;
    }
} t;

```

4.2 AC 自动机

注意 AC 自动机与 trie 不同的地方在于，根必须是 0。

题意：给你一个文本串 S 和 n 个模式串 $T_1 \sim T_n$ ，请你分别求出每个模式串 T_i 在 S 中出现的次数。

```

struct AC
{
    const static int N = 3e6 + 2, M = 26;
    int c[N][M], sz[N], pos[N], f[N], app[N]; //sz 维护有多少个以当前字符串为前缀的字符串。
    int cnt = 0, id = 0;
    vector<int> q;
    void insert(string s)
    {

```

```

    int u = 0;
    ++sz[u];
    for (char ch : s)
    {
        assert(ch >= 0 && ch < M);
        int &v = c[u][ch];
        if (!v) v = ++cnt;
        u = v;
        ++sz[u];
    }
    pos[id++] = u;
    //此时 u 是字符串结束位置。你可以在此存储结点信息。
}
vector<int> match(string s)//返回答案。复杂度 O(结点数)
{
    int u = 0, i;
    for (char ch : s)
    {
        assert(ch >= 0 && ch < M);
        u = c[u][ch];
        ++app[u];
    }

cin >> t;
for (char &c : t) c -= 'a';
auto res = s.match(t);
for (int x : res) cout << x << '\n';
}

```

4.3 hash

在调试时，可以把 `base` 设置为 10 的幂方便输出。可能建议把第一个模数也设置为 1，但未测试是否有奇怪的问题。但要注意，此时不应当使用接近 10 的幂次的模数。

$O(n)$, $O(n)$ 。

建议抄 `int128` 版本。目前来看，`int128` 版本的既好写又快。

`__int128` 版本：

```

namespace sh
{
    using ull = unsigned long long;
    using lll = __uint128_t;
    const int N = 1e6 + 5;
    const ull p = (ull)1e18 - 11, b = 137;
    ull m[N];
    int i = []() {
        m[0] = 1;
        for (int i = 1; i < N; i++) m[i] = (lll)m[i - 1] * b % p;
        return 0;
    }();
    struct str
    {
        int n;
        vector<ull> a;
        template<class T> str(const vector<T> &s) : n(s.size()), a(n + 1)
        {
            for (i = 0; i < n; i++) a[i + 1] = ((lll)a[i] * b + s[i]) % p;
        }
        template<class T> str(const basic_string<T> &s) : n(s.size()), a(n + 1) //直接去掉模板换成
string 也可以
        {
            for (i = 0; i < n; i++) a[i + 1] = ((lll)a[i] * b + s[i]) % p;
        }
        ull getv(int l, int r) //[l,r)
        {
            return (a[r] + (lll)(p - a[l]) * m[r - l]) % p;
        }
        int lcp(int i, int j)
        {

```

```

        if (i == j) return n - i;
        int l = 0, r = n - max(i, j), mid;
        while (l < r)
        {
            mid = (l + r + 1) >> 1;
            if (getv(i, i + mid) == getv(j, j + mid)) l = mid;
            else r = mid - 1;
        }
        return l;
    }
};
}
using sh::str;

```

双模数版本：

特别注意这里 m 数组预处理的不是幂次，而是幂次的相反数。

其返回值是两个 32 位数拼接而成的，要改动比较麻烦。

```

namespace sh
{
    using ui = unsigned int;
    using ull = unsigned long long;
    const int N = 1e6 + 5;
    const ui p1 = 2'034'452'107, p2 = 2'013'074'419;
    struct pa
    {

```

4.10 Z 函数

表示每个后缀和母串的 lcp。

```

vector<int> Z(const string &s)
{
    int n = s.size(), i, l, r;
    vector<int> z(n);
    z[0] = n;
    for (i = 1, l = r = 0; i < n; i++)
    {
        if (i <= r && z[i - l] < r - i + 1) z[i] = z[i - l];
        else
        {
            z[i] = max(0, r - i + 1);
            while (i + z[i] < n && s[i + z[i]] == s[z[i]]) ++z[i];
        }
        if (i + z[i] - 1 > r) l = i, r = i + z[i] - 1;
    }
    return z;
}

```

4.11 最小表示法

找到一个串的循环同构串中字典序最小的那个，将这个串直接变过去。常见应用：环哈希（基环树哈希）。

如果只需要找到起点下标，在 `rotate` 前返回 $\min\{i, j\}$ 即可。

$O(n)$, $O(1)$ 。

```
template<class T> void min_order(vector<T>& a)
{
    int n = a.size(), i, j, k;
    a.resize(n * 2);
    for (i = 0; i < n; i++) a[i + n] = a[i];
    i = k = 0; j = 1;
    while (i < n && j < n && k < n)
    {
        T x = a[i + k], y = a[j + k];
        if (x == y) ++k; else
        {
            (x > y ? i : j) += k + 1;
            j += (i == j);
            k = 0;
        }
    }
    a.resize(n);
    // [min(i, j), n) + [0, min(i, j))
    rotate(a.begin(), min(i, j) + all(a));
}
```

4.12 带通配符的字符串匹配

原理：匹配等价于 $\sum (f_i - g_i)^2 = 0$ 。带通配符等价于 $\sum f_i g_i (f_i - g_i)^2 = 0$ ，展开即可。

这里也是较为推荐的 NTT 版本，直接实现任意长度的多项式相乘，便于一般情况的运用。不需要提前做任何 init。

```
namespace NTT
{
    typedef unsigned ui;
    typedef unsigned long long ull;
    const int N = 1 << 22;
    const ui p = 998244353, g = 3;
    inline ui ksm(ui x, ui y)
    {
        ui ans = 1;
        while (y)
        {
            if (y & 1) ans = 1llu * ans * x % p;
            y >>= 1; x = 1llu * x * x % p;
        }
        return ans;
    }
    ui r[N], w[N];
    void ntt(vector<ui> &a)
    {
        int n = a.size(), i, j, k;
        for (i = 0; i < n; i++) if (i < r[i]) swap(a[i], a[r[i]]);
        for (k = 1; k < n; k <= 1)
```

```

    {
        for (i = 0; i < n; i += k << 1)
        {
            for (j = 0; j < k; j++)
            {
                ui x = a[i + j], y = 1llu * a[i + j + k] * w[j + k] % p;
                a[i + j] = (x + y) % p; a[i + j + k] = (x + p - y) % p;
            }
        }
    }
}

vector<ui> mul(vector<ui> a, vector<ui> b)
{
    if (a.size() == 0 || b.size() == 0) return { };
    int m = a.size() + b.size() - 1;
    int n = 1 << __lg(m * 2 - 1);
    int i, j, base = __lg(n) - 1;
    ui inv = ksm(n, p - 2);
    for (i = 1; i < n; i++) r[i] = r[i >> 1] >> 1 | (i & 1) << base;
    for (j = 1; j < n; j <= 1)
    {
        ui wn = ksm(3, (p - 1) / (j << 1));
        w[j] = 1;
        for (i = 1; i < j; i++) w[j + i] = 1llu * w[j + i - 1] * wn % p;
    }
    a.resize(n); b.resize(n);
    ntt(a); ntt(b);
    for (i = 0; i < n; i++) a[i] = 1llu * a[i] * b[i] % p;
    ntt(a); reverse(1 + all(a)); a.resize(n = m);
    for (i = 0; i < n; i++) a[i] = 1llu * a[i] * inv % p;
    return a;
}

vector<int> match(const string &s, const string &t)
{
    using NTT::p, NTT::mul;
    static mt19937 rnd(chrono::steady_clock::now().time_since_epoch().count());
    static array<ui, 256> c;
    static bool initd = 0;
    if (!initd)
    {
        initd = 1;
        for (ui &x : c) x = rnd() % NTT::p;
        c['*'] = 0; //通配符
    }
    int n = s.size(), m = t.size(), i, j;
    if (n < m) return { };
    vector<int> ans;
    vector<ui> f(n), ff(n), fff(n), g(m), gg(m), ggg(m);
    for (i = 0; i < n; i++)
    {
        f[i] = c[s[i]];
        ff[i] = 1llu * f[i] * f[i] % p;
        fff[i] = 1llu * ff[i] * f[i] % p;
    }
    for (i = 0; i < m; i++)
    {

```

```

        g[i] = c[t[m - i - 1]];
        gg[i] = 1llu * g[i] * g[i] % p;
        ggg[i] = 1llu * gg[i] * g[i] % p;
    }
    auto fffg = mul(fff, g), ffgg = mul(ff, gg), fggg = mul(f, ggg);
    for (i = 0; i <= n - m; i++) if ((fffg[m - 1 + i] + fggg[m - 1 + i] + 2 * (NTT::p - ffgg[m - 1 + i])) % NTT::p == 0) ans.push_back(i);
    return ans;
}

```

快一些的版本，手动拆开了多项式乘法。

```

const int N = 1 << 22;
const ui p = 998244353, g = 3;
inline ui ksm(ui x, ui y)

return ans;
}

```

5 图论

5.1 最小生成树相关

5.1.1 切比雪夫距离最小生成树

原理：先转曼哈顿距离，再用曼哈顿的板子。

$O(n \log n)$, $O(n)$ 。

```
const int N = 3e5 + 2, M = N << 2;
struct P
{
    int u, v, w;
    P(int a = 0, int b = 0, int c = 0) : u(a), v(b), w(c) { }
    bool operator<(const P &o) const { return w < o.w; }
};
struct Q
{
    int x, y, id;
    Q(int a = 0, int b = 0, int c = 0) : x(a), y(b), id(c) { }
    bool operator<(const Q &o) const { return x != o.x ? x > o.x : y > o.y; }
};
ll ans;
P lb[M];
Q a[N], b[N];
int f[N], c[N];
int n, m, i, x, y;
struct bit
{
    int a[N], pos[N], n;
    void init(int &nn)
    {
        memset(a + 1, 0x7f, (n = nn) * sizeof a[0]);
        memset(pos + 1, 0, n * sizeof pos[0]);
    }
    void mdf(int x, const int y, const int z)
    {
        if (a[x] > y) a[x] = y, pos[x] = z;
        while (x -= x & -x) if (a[x] > y) a[x] = y, pos[x] = z;
    }
    int sum(int x)
    {
        int r = a[x], rr = pos[x];
        while ((x += x & -x) <= n) if (a[x] < r) r = a[x], rr = pos[x];
        return rr;
    }
};
bit s;
void cal()
{
    int i, x, y;
    s.init(n);
    memcpy(b + 1, a + 1, sizeof(Q) * n);
    sort(a + 1, a + n + 1);
    for (i = 1; i <= n; i++) c[i] = a[i].y - a[i].x;
    sort(c + 1, c + n + 1);
    for (i = 1; i <= n; i++)
```

```

    cout << ans / 2 << endl;
}

```

5.1.2 最小乘积生成树

题意：每条边有两个属性 x_i, y_i ，你需要最小化 $(\sum x_i)(\sum y_i)$ 。

你需要实现的是 sol1，即按照 val 为权值的答案。 val_i 是根据 x_i, y_i 计算的。

```

#include "bits/stdc++.h"
using namespace std;
typedef long long ll;
const int N = 202, M = 10002;
struct P
{
    int x, y;
    P(int a = 0, int b = 0) : x(a), y(b) { }
    bool operator<(const P &o) const { return (ll)x * y < (ll)o.x * o.y || (ll)x * y == (ll)o.x * o.y && x < o.x; }
};
struct Q
{
    int u, v, x, y, val;
    bool operator<(const Q &o) const { return val < o.val; }
};
P ans = P(1e9, 1e9), l, r;
Q a[M];
int f[N];
int n, m, i;
int getf(int x)
{
    if (f[x] == x) return x;
    return f[x] = getf(f[x]);
}
P sol1()
{
    P r = P(0, 0);

```

```

for (i = 1; i <= n; i++) f[i] = i;
sort(a + 1, a + m + 1);
for (i = 1; i <= m; i++) if (getf(a[i].u) != getf(a[i].v))
{
    f[f[a[i].u]] = f[a[i].v];
    r.x += a[i].x, r.y += a[i].y;
}
return r;
}
void sol2(P l, P r)
{
    for (i = 1; i <= m; i++) a[i].val = (r.x - l.x) * a[i].y + (l.y - r.y) * a[i].x;
    P np = sol1();
    ans = min(ans, np);
    if ((ll)(r.x - l.x) * (np.y - l.y) - (ll)(r.y - l.y) * (np.x - l.x) >= 0) return;
    sol2(l, np); sol2(np, r);
}
int main()
{
    cin >> n >> m;
    for (i = 1; i <= m; i++) cin >> a[i].u >> a[i].v >> a[i].x >> a[i].y, ++a[i].u, ++a[i].v;
    for (i = 1; i <= m; i++) a[i].val = a[i].x; l = sol1();
    for (i = 1; i <= m; i++) a[i].val = a[i].y; r = sol1();
    ans = min(ans, min(l, r)); sol2(l, r);
    cout<<ans.x<<'␣'<<ans.y<<endl;
}

```

5.1.3 最小斯坦纳树

题意：让给定点集连通的最小生成树（不要求全图连通）

$O(3^k n + 2^k m \log m)$ 。

分为有方案与无方案两个版本，点标号 $[0, n)$ 。

```

ll steiner(int n, const vector<tuple<int, int, ll>> &eg, vector<int> id)//[0,n)
{
    using pa = pair<ll, int>;
    int m = id.size(), i;
    vector f(1 << m, vector<ll>(n, inf));
    for (i = 0; i < m; i++) f[1 << i][id[i]] = 0;
    vector<vector<pair<int, ll>>> e(n);
    for (auto [u, v, w] : eg) e[u].push_back({v, w}), e[v].push_back({u, w});
    for (int S = 1; S < 1 << m; S++)
    {
        auto &d = f[S];
        priority_queue<pa, vector<pa>, greater<pa>> q;
        for (i = 0; i < n; i++)
        {
            for (int T = S - 1 & S; T; T = T - 1 & S) cmin(d[i], f[T][i] + f[S ^ T][i]);
            if (d[i] != inf) q.push({d[i], i});
        }
        while (q.size())
        {
            auto [_, u] = q.top(); q.pop();
            if (_ != d[u]) continue;
            for (auto [v, w] : e[u]) if (cmin(d[v], d[u] + w)) q.push({d[v], v});
        }
    }
}

```

```

    }
    return *min_element(all(f.back()));
}

pair<ll, vector<int>> steiner_construct(int n, const vector<tuple<int, int, ll>> &eg, vector<int>

cout << ans << '□' << eid.size() << '\n' << eid << endl;
}

```

5.2 最短路相关

5.2.1 全源最短路与判负环

使用 floyd 实现全源最短路与判负环。注意边权较大时可能需要考虑 int128.

```

#include "bits/stdc++.h"
using namespace std;
typedef long long ll;
typedef pair<int,int> pa;
typedef tuple<int,int,int> tp;
const int N=152;
const ll inf=5e8;
ll dis[N][N],d[N][N];
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    while (1)
    {
        int n,m,q,i,j,k;
        cin>>n>>m>>q;
        if (tp(n,m,q)==tp(0,0,0)) return 0;
        for (i=0;i<n;i++) fill_n(dis[i],n,inf*inf);
        for (i=0;i<n;i++) dis[i][i]=0;
        while (m--)
        {
            int u,v,w;
            cin>>u>>v>>w;
            dis[u][v]=min(dis[u][v],(ll)w);
        }
        for (k=0;k<n;k++) for (i=0;i<n;i++) for (j=0;j<n;j++) dis[i][j]=max(min(dis[i][j],dis[i][k]+dis[k][j]),-inf*2);
        for (i=0;i<n;i++) copy_n(dis[i],n,d[i]);
        for (k=0;k<n;k++) for (i=0;i<n;i++) for (j=0;j<n;j++) dis[i][j]=max(min(dis[i][j],dis[i][k]+dis[k][j]),-inf*2);
        while (q--)
        {
            int u,v;
            cin>>u>>v;
            if (d[u][v]>inf) cout<<"Impossible\n"; else if (dis[u][v]!=d[u][v] || d[u][v]<-inf)
            cout<<"-Infinity\n"; else cout<<d[u][v]<<'\n';
        }
        cout<<'\n';
    }
}

```

5.2.2 Dijkstra/SPFA/Johnson

Johnson 不适用于图中存在负环的情况，因为负环不一定是可以经过的。

$O(nm \log m)$, $O(n + m)$ 。

```
vector<ll> spfa(const vector<vector<pair<int, ll>>> &e, int s)
{
    int n=e.size(), i;
    assert(n);
    queue<int> q;
    vector<int> len(n), ed(n);
    vector<ll> dis(n, inf);
    q.push(s); dis[s]=0;
    while (q.size())
    {
        int u=q.front(); q.pop();
        ed[u]=0;
        for (auto [v, w]:e[u]) if (cmin(dis[v], dis[u]+w))
        {
            len[v]=len[u]+1;
            if (len[v]>n) return { };
            if (!ed[v])
            {
                ed[v]=1;
                q.push(v);
            }
        }
    }
    return dis;
}

vector<ll> spfa(const vector<vector<pair<int, ll>>> &e)
{
    int n=e.size(), i;
    assert(n);
    queue<int> q;
    vector<int> len(n), ed(n, 1);
    vector<ll> dis(n);
    for (i=0; i<n; i++) q.push(i);
    while (q.size())
    {
        int u=q.front(); q.pop();
        ed[u]=0;
        for (auto [v, w]:e[u]) if (cmin(dis[v], dis[u]+w))
        {
            len[v]=len[u]+1;
            if (len[v]>n) return { };
            if (!ed[v])
            {
                ed[v]=1;
                q.push(v);
            }
        }
    }
    return dis;
}

vector<ll> dijk(const vector<vector<pair<int, ll>>> &e, int s)
{
    int n=e.size();
```

```

using pa=pair<ll, int>;
vector<ll> d(n, inf);
vector<int> ed(n);
priority_queue<pa, vector<pa>, greater<pa>> q;
d[s]=0; q.push({0, s});
while (q.size())
{
    int u=q.top().second; q.pop();
    ed[u]=1;
    for (auto [v, w]:e[u]) if (cmin(d[v], d[u]+w)) q.push({d[v], v});
    while (q.size() && ed[q.top().second]) q.pop();
}
return d;
}
vector<vector<ll>> dijk(const vector<vector<pair<int, ll>>> &e)
{
    vector<vector<ll>> r;
    for (int i=0; i<e.size(); i++) r.push_back(dijk(e, i));
    return r;
}
vector<vector<ll>> john(vector<vector<pair<int, ll>>> e)
{
    int n=e.size(), i, j;
    assert(n);
    auto h=spfa(e);
    if (!h.size()) return { };
    for (i=0; i<n; i++) for (auto &[v, w]:e[i]) w+=h[i]-h[v];
    auto r=dijk(e);
    for (i=0; i<n; i++) for (j=0; j<n; j++) if (r[i][j]!=inf) r[i][j]-=h[i]-h[j];
    return r;
}

```

5.2.3 无向图最小环

原理：floyd 外层循环本质是计算只经过 $\leq k$ 的点的最短路。因此枚举环上标号最大的，在做这一轮转移之前正好是不经过它的最短路。

$O(n^3)$, $O(n^2)$ 。

```

int f[N][N], j1[N][N];
int n, m, c, ans=inf, i, j, k, x, y, z;
int main()
{
    cin>>n>>m;
    memset(f, 0x3f, sizeof(f));
    memset(j1, 0x3f, sizeof(j1));
    while (m--)
    {
        cin>>x>>y>>z;
        j1[x][y]=j1[y][x]=f[x][y]=f[y][x]=min(f[y][x], z);
    }
    for (k=1; k<=n; k++)
    {
        for (i=1; i<k; i++) if (j1[k][i]!=j1[0][0]) for (j=1; j<i; j++)
            if (j1[k][j]!=j1[0][0]) ans=min(ans, j1[k][i]+j1[k][j]+f[i][j]);
        for (i=1; i<=n; i++) if (i!=k) for (j=1; j<=n; j++)
            if ((j!=i) && (j!=k)) f[i][j]=min(f[i][j], f[i][k]+f[k][j]);
    }
}

```

```

}
if (ans==inf) cout<<"No solution.\n"; else cout<<ans<<endl;
}

```

5.2.4 输出负环

```

#include "bits/stdc++.h"
using namespace std;
const int N = 34;
struct Q
{
    int v, w, c;
    Q() { }
    Q(int x, int y, int z) :v(x), w(y), c(z) { }
};
vector<Q> lj[N];
int dis[N], cnt[N], pt[N], S;
Q pre[N], st[N];
int n, m, ans, tp;
bool ed[N];
int main()
{
    freopen("arbitrage.in", "r", stdin);
    freopen("arbitrage.out", "w", stdout);
    ios::sync_with_stdio(0); cin.tie(0);
    cin >> n >> m;
    while (m--)
    {
        int x, y, z, w;
        cin >> x >> y >> z >> w;
        lj[x].emplace_back(y, w, z);
        lj[y].emplace_back(x, 0, -z);
    }
    for (int i = 1; i <= n; i++) lj[0].emplace_back(i, 1, 0);
    while (1)
    {
        memset(dis, -0x3f, sizeof dis); dis[0] = 0;
        for (int i = 0; i <= n; i++) ed[i] = cnt[i] = 0; S = -1;
        queue<int> q; q.push(0);
        while (!q.empty())
        {
            int u = q.front(); q.pop(); ed[u] = 0;
            for (auto &[v, w, c] : lj[u]) if (w && dis[v] < dis[u] + c)
            {
                dis[v] = dis[u] + c; pre[v] = Q(u, w, c);
                if (!ed[v])
                {
                    if (++cnt[v] > n + 1) { S = v; goto aa; }
                    ed[v] = 1; q.push(v);
                }
            }
        }
    }
aa:;
    if (S == -1) break;
    {
        static bool ed[N];

```

```

        memset(ed, 0, sizeof ed);
        while (!ed[S]) ed[S] = 1, S = pre[S].v;
    }
    st[tp = 1] = pre[S]; pt[1] = S;
    int x = pre[S].v;
    while (x != S)
    {
        st[++tp] = pre[x]; pt[tp] = x;
        x = pre[x].v;
        assert(tp <= n + 5);
    }
    int fl = 1e9;
    for (int j = 1; j <= tp; j++) fl = min(fl, st[j].w);
    assert(fl);
    for (int j = 1; j <= tp; j++)
    {
        ans += fl * st[j].c;
        int nn = 0;
        for (auto &[v, w, c] : lj[st[j].v]) if (v == pt[j] && st[j].c == c && st[j].w == w) {
            ++nn; w -= fl; break; }
        for (auto &[v, w, c] : lj[pt[j]]) if (v == st[j].v && st[j].c + c == 0) { ++nn; w +=
            fl; break; } assert(nn == 2);
    }
}
cout << ans << endl;
}

```

5.3 二分图与网络流建图

以下约定，若为二分图则 n, m 表示两侧点数，否则仅 n 表示全图点数。

5.3.1 二分图边染色

留坑待填。

结论： $\Delta(G) \leq \chi'(G) \leq \Delta(G) + 1$ ，二分图时 $\chi'(G) = \Delta(G)$ 。 $\Delta(G)$ 为图的最大度。

5.3.2 二分图最小点集覆盖

$ans = \text{maxmatch}$ ，方案如下。

```

#include "bits/stdc++.h"
using namespace std;
const int N = 5e3 + 2;
vector<int> e[N];
int ed[N], lk[N], kl[N], flg[N], now;
bool dfs(int u)
{
    for (int v : e[u]) if (ed[v] != now)
    {
        ed[v] = now;
        if (!lk[v] || dfs(lk[v])) return lk[v] = u;
    }
    return 0;
}
void dfs2(int u)
{
}

```

```

    for (int v : e[u]) if (!flg[v]) flg[v] = 1, dfs2(lk[v]);
}
int main()
{
    int n, m, i, r = 0;
    cin >> n >> m;
    while (m--)
    {
        int u, v;
        cin >> u >> v;
        e[u].push_back(v);
    }
    for (i = 1; i <= n; i++) dfs(now = i);
    for (i = 1; i <= n; i++) kl[lk[i]] = i;
    for (i = 1; i <= n; i++) if (!kl[i]) dfs2(i);
    vector<int> A[2];
    for (i = 1; i <= n; i++) if (lk[i])
    {
        if (flg[i]) A[1].push_back(i); else A[0].push_back(lk[i]);
    }
    for (int j = 0; j < 2; j++)
    {
        cout << A[j].size();
        for (int x : A[j]) cout << ' ' << x; cout << '\n';
    }
}

```

5.3.3 二分图最大独立集

$ans = n + m - \text{maxmatch}$, 方案是最小点集覆盖的补集。

5.3.4 二分图最小边覆盖

$ans = n + m - \text{maxmatch}$, 方案是最大匹配加随便一些边（用于覆盖失配点）。无解当且仅当有孤立点，算法会视为单选孤立点（无边）。这个定理对一般图也成立。

5.3.5 有向无环图最小不相交链覆盖

$ans = n - \text{maxmatch}$, 其中二分图建图方法是拆入点和出点（实现时直接跑一次二分图就行，不用额外处理），注意不需要传递闭包。方案如下。

```

#include "bits/stdc++.h"
using namespace std;
const int N = 152;
vector<int> e[N];
int lk[N], kl[N], ed[N], now;
bool dfs(int u)
{
    for (int v : e[u]) if (ed[v] != now)
    {
        ed[v] = now;
        if (!lk[v] || dfs(lk[v])) return lk[v] = u;
    }
    return 0;
}
int main()

```

```

{
    int n, m, i;
    ios::sync_with_stdio(0); cin.tie(0);
    cin >> n >> m;
    while (m--)
    {
        int u, v;
        cin >> u >> v;
        e[u].push_back(v);
    }
    int r = 0;
    for (i = 1; i <= n; i++) r += dfs(now = i);
    for (i = 1; i <= n; i++) kl[lk[i]] = i;
    for (i = 1; i <= n; i++) if (ed[i] != -1 && !lk[i])
    {
        vector<int> ans;
        int u = i;
        while (u)
        {
            ed[u] = -1;
            ans.push_back(u);
            u = kl[u];
        }
        for (int j = 0; j < ans.size(); j++) cout << ans[j] << "\n"[j + 1 == ans.size()];
    }
    cout << n - r << endl;
}

```

5.3.6 有向无环图最大互不可达集

$ans = n - \text{maxmatch}$, 其中二分图建图方法是拆入点和出点 (实现时直接跑一次二分图就行, 不用额外处理), 注意需要传递闭包。方案?

5.3.7 最大权闭合子图

若 $v_i > 0$, $s \rightarrow i$ 流量 v_i ; 若 $v_i < 0$, $i \rightarrow t$ 流量 $-v_i$ 。若原图 $u \rightarrow v$ 可花费 w 代价违抗, 流量 w , 否则 $+\infty$ 。答案为 $\sum_{v_i > 0} v_i - \text{maxflow}$ 。方案?

5.4 匹配与网络流相关代码

5.4.1 二分图最大权匹配

```

namespace KM
{
    const int N = 405; // 点数
    typedef long long ll; // 答案范围
    const ll inf = 1e16;
    int lk[N], kl[N], pre[N], q[N], n, h, t;
    ll sl[N], e[N][N], lx[N], ly[N];
    bool edx[N], edy[N];
    bool ck(int v)
    {
        if (edy[v] = 1, lk[v]) return edx[q[++t]] = kl[v]] = 1;
        while (v) swap(v, lk[kl[v] = pre[v]]);
        return 0;
    }
}

```

```

}
void bfs(int u)
{
    fill_n(sl + 1, n, inf);
    memset(edx + 1, 0, n * sizeof edx[0]);
    memset(edy + 1, 0, n * sizeof edy[0]);
    q[h = t = 1] = u; edx[u] = 1;
    while (1)
    {
        while (h <= t)
        {
            int u = q[h++], v;
            ll d;
            for (v = 1; v <= n; v++) if (!edy[v] && sl[v] >= (d = lx[u] + ly[v] - e[u][v]))
if (pre[v] = u, d) sl[v] = d; else if (!ck(v)) return;
        }
        int i;
        ll m = inf;
        for (i = 1; i <= n; i++) if (!edy[i]) m = min(m, sl[i]);
        for (i = 1; i <= n; i++)
        {
            if (edx[i]) lx[i] -= m;
            if (edy[i]) ly[i] += m; else sl[i] -= m;
        }
        for (i = 1; i <= n; i++) if (!edy[i] && !sl[i] && !ck(i)) return;
    }
}
template<class TT> ll max_weighted_match(int N, const vector<tuple<int, int, TT>> &edges)//lk
[[1,n]]->[1,n]
{
    int i; n = N;
    memset(lk + 1, 0, n * sizeof lk[0]);
    memset(kl + 1, 0, n * sizeof kl[0]);
    memset(ly + 1, 0, n * sizeof ly[0]);
    for (i = 1; i <= n; i++) fill_n(e[i] + 1, n, 0); // 若不需保证匹配边最多, 置 0 即可, 否则 -
inf/N
    for (auto [u, v, w] : edges) e[u][v] = max(e[u][v], (ll)w);
    for (i = 1; i <= n; i++) lx[i] = *max_element(e[i] + 1, e[i] + n + 1);
    for (i = 1; i <= n; i++) bfs(i);
    ll r = 0;
    for (i = 1; i <= n; i++)
        if (!e[i][lk[i]]) // 若不需保证匹配边最多, 需要去掉这些辅助边
            kl[lk[i]] = 0, lk[i] = 0;
        else
            r += e[i][lk[i]];
    return r;
}
}
using KM::max_weighted_match, KM::lk, KM::kl, KM::e;

```

5.4.2 一般图最大匹配

```

5.4.5 假带花树

一种错误的一般图最大匹配算法，但较难卡掉。推荐在时间不足时作为乱搞使用。

```

mt19937 rnd(3214);
vector<int> lj[N];
int lk[N], ed[N];
int n, m, cnt, i, t, x, y, ans, la;
bool dfs(int x)
{

```

```

ed[x] = cnt; int v;
shuffle(lj[x].begin(), lj[x].end(), rnd);
for (auto u : lj[x]) if (ed[v = lk[u]] != cnt)
{
    lk[v] = 0, lk[u] = x, lk[x] = u;
    if (!v || dfs(v)) return 1;
    lk[v] = u, lk[u] = v, lk[x] = 0;
}
return 0;
}
int main()
{
    srand(time(0)); la = -1;
    cin >> n >> m;
    while (m--) cin >> x >> y, lj[x].push_back(y), lj[y].push_back(x);
    while (la != ans)
    {
        memset(ed + 1, 0, n << 2); la = ans;
        for (i = 1; i <= n; i++) if (!lk[i]) ans += dfs(cnt = i);
    }
    cout << ans << '\n';
    for (i = 1; i <= n; i++) cout << lk[i] << "□\n"[i == n];
}

```

5.4.6 Stoer-Wagner 全局最小割

无向图 G 的最小割为：一个去掉后可以使 G 变成两个连通分量，且边权和最小的边集的边权和。

$O(n^3)$ 。可优化到 $O(nm \log n)$ 。

```

#include "bits/stdc++.h"
using namespace std;
namespace StoerWagner
{
    const int N = 602; // 点数
    typedef int T; // 边权和
    T e[N][N], w[N];
    int ed[N], p[N], f[N]; // f 仅输出方案用
    int getf(int u) { return f[u] == u ? u : f[u] = getf(f[u]); }
    template<class TT> pair<T, vector<int>> mincut(int n, const vector<tuple<int, int, TT>> &
edges) // [1,n], 返回某一集合
    {
        vector<int> ans; ans.reserve(n);

for (i = 0; i < n; i++) if (i != s && i != t && (!cd[i] || !rd[i])) return { };
return a;
}

```

5.5.2 点双

一些结论：

判定一个图里是否有（点不重复）偶环：看其所有点双，若存在点数为偶数的或边数多于点数的点双，则存在偶环。

（无自环时）点双的边不交，边双的点不交。点双内的总点数 $O(n)$ ，总边数为 m ，边双内的总点数为 n ，总边数不超过 m 。

关于板子本身：

所有标号从 0 开始。

构造函数传入邻接表和边数，其中 pair 的 second 是边的标号，正反向编号相同，允许不连续但不能大于等于 m 。

不能处理有自环的情况。你可以直接在图中删除自环后传入。可以处理有重边的情况。

bcc_node：每个点双包含的点（已验证）；bcc_edge：每个点双包含的边；bcc_n：新图点数；ct：是否割点（已验证）；blk：边所属点双标号。

```

struct node_bcc
{
    int n, id, tp, bcc_n;
    vector<vector<pair<int, int>>> e;
    vector<vector<int>> bcc_node, bcc_edge;
    vector<int> dfn, low, st, ed, blk, ct;

    }
}

```

5.5.4 Tarjan 强连通分量

未经验证。

所有标号从 0 开始。

构造函数传入邻接表，其中 `pair` 的 `second` 是边的标号。

与点边双不同的是，你可以任意传入 `second`，代码中不会使用它，仅用于新图区分边。

可以处理有重边和自环的情况。

`cc_node`: 每个 SCC 包含的点（已验证）；`cc_n`: 新图点数；`cur_e`: 新图边表；`blk`: 点所属 SCC 标号。

```

struct scc
{
    int n, id, tp, cc_n;
    vector<vector<pair<int, int>>> e, cur_e;
    vector<vector<int>> cc_node;
    vector<int> dfn, low, st, ed, blk;
    void dfs(int u)
    {
        dfn[u] = low[u] = id++;
        st[tp++] = u; ed[u] = 1;
        for (auto [v, w] : e[u]) if (dfn[v] == -1)
        {
            dfs(v);
            cmin(low[u], low[v]);
        }
        else if (ed[v]) cmin(low[u], dfn[v]);
        if (low[u] == dfn[u])
    }
}

```

```

    {
        cc_node.push_back({ });
        do
        {
            int v = st[--tp];
            ed[v] = 0;
            blk[v] = cc_n;
            cc_node[cc_n].push_back(v);
        } while (st[tp] != u);
        cc_n++;
    }
}
scc(const vector<vector<pair<int, int>>> &e) :n(e.size()), id(0), tp(0), cc_n(0),
    e(e), cur_e(n), dfn(n, -1), low(dfn), st(n), ed(n), blk(n)
{
    for (int i = 0; i < n; i++) for (auto [v, w] : e[i]) assert(v >= 0 && v < n);
    for (int i = 0; i < n; i++) if (dfn[i] == -1) dfs(i);
    reverse(all(cc_node));
    for (int &x : blk) x = cc_n - x - 1;
    for (int u = 0; u < n; u++)
        for (auto [v, w] : e[u])
            if (blk[u] != blk[v])
                cur_e[blk[u]].push_back({blk[v], w});
    cur_e.resize(cc_n);
}
};
vector<vector<int>> unique(vector<vector<pair<int, int>>> &e)
{
    int n = e.size(), i;
    vector<vector<int>> g(n);
    for (i = 0; i < n; i++)
    {
        for (auto [v, w] : e[i]) g[i].push_back(v);
        sort(all(g[i]));
        g[i].resize(unique(all(g[i])) - g[i].begin());
    }
    return g;
}

```

5.5.5 动态强连通分量

给出一个加边序列，solve 会返回每个时间进入强连通分量的边。点标号范围是 $[0, n)$

```

struct union_set
{
    vector<int> f;
    int n;
    union_set() { }
    union_set(int nn) :n(nn), f(nn + 1)
    {
        iota(all(f), 0);
    }
    int getf(int u) { return f[u] == u ? u : f[u] = getf(f[u]); }
    bool merge(int u, int v)
    {
        u = getf(u); v = getf(v);
    }
}

```

```

        if (u == v) return 0;
        f[u] = v;
        return 1;
    }
    bool connected(int u, int v) { return getf(u) == getf(v); }
};

struct edge
{
    int u, v, t;
};

vector<vector<edge>> solve(int n, const auto &eg)//[0,n)
{
    int m = eg.size(), tp = -1, id = 0, fs = 0;
    vector<vector<edge>> res(m);
    vector e(n, vector<int>());
    vector<int> dfn(n, -1), low(n, -1), st(n), ed(n), blk(n), node;
    union_set s(n - 1);
    function<void(int)> dfs = [&](int u) {

5.5.7 广义圆方树

建议使用点双来做这个。你只需要对每个点双建一个虚点，向点双内所有原点连边，就得到了广义圆方树。

```

void dfs(int u)
{
    dfn[u] = low[u] = ++id;
    st[++tp] = u;
    for (int v : e[u]) if (dfn[v]) low[u] = min(low[u], dfn[v]); else
    {
        dfs(v);
        low[u] = min(low[u], low[v]);
        if (dfn[u] <= low[v])
        {
            vector cur = {u};
            do
            {
                cur.push_back(st[tp]);
            } while (st[tp--] != v);
            ans.push_back(cur);
        }
    }
}
}

```

5.5.8 2-sat

支持添加一个条件 $\text{add}(u, x, v, y)$ ，表示 $a_u = x \Rightarrow a_v = y$ 。支持设定一个变量的值。
 $O(n + m)$, $O(n + m)$ 。

```

struct sat
{
    vector<vector<int>> e;
    vector<int> dfn, low, st, f, ed;
    int fs, tp, id, n;
    sat(int n) : n(n), e(n * 2), dfn(n * 2, -1), low(n * 2), st(n * 2), f(n * 2, -1), ed(n * 2),
    fs(0), tp(-1), id(0) { }
    void dfs(int u)
    {
        dfn[u] = low[u] = id++;
        ed[u] = 1; st[++tp] = u;
        for (int v : e[u]) if (dfn[v] != -1)
        {
            if (ed[v]) low[u] = min(low[u], dfn[v]);
        }
        else dfs(v), low[u] = min(low[u], low[v]);
        if (dfn[u] == low[u])
        {

```

```

        do
        {
            f[st[tp]] = fs;
            ed[st[tp]] = 0;
        } while (st[tp--] != u);
        ++fs;
    }
}

void add(int u, bool x, int v, bool y)
{
    assert(u >= 0 && u < n && v >= 0 && v < n);
    e[u + x * n].push_back(v + y * n);
    e[v + (y ^ 1) * n].push_back(u + (x ^ 1) * n);
}

void set(int u, bool x)
{
    assert(u >= 0 && u < n);
    e[u + (x ^ 1) * n].push_back(u + x * n);
}

vector<int> getans()
{
    int i;
    for (i = 0; i < n * 2; i++) if (dfn[i] == -1) dfs(i);

    }
    return r;
}
};

```

5.5.9 Kosaraju 强连通分量 (bitset 优化)

实用意义不大。

$O(\frac{n^2}{w})$, $O(\frac{n^2}{w})$ 。

```

void dfs1(int x)
{
    int i; ed[x] = 0;
    for (i = (lj[x] & ed)._Find_first(); i <= n; i = (lj[x] & ed)._Find_next(i)) dfs1(i);
    sx[--tp] = x;
}

void dfs2(int x)
{
    int i; ed[x] = 0; tv[f[x] = f[0]] += v[x];
    for (i = (fj[x] & ed)._Find_first(); i <= n; i = (fj[x] & ed)._Find_next(i)) dfs2(i);
}

int main()
{
    cin >> n >> m;
    tp = n + 1;
    for (i = 1; i <= n; i++) { ed[i] = 1; cin >> v[i]; }
    for (i = 1; i <= m; i++)
    {
        cin >> x >> y;
    }
}

```

```

    lj[x][y] = 1; fj[y][x] = 1; lb[i][0] = x; lb[i][1] = y;
}
for (i = 1; i <= n; i++) if (ed[i]) dfs1(i);
ed.set();
for (i = 1; i <= n; i++) if (ed[sx[i]]) { ++f[0]; dfs2(sx[i]); }
for (i = 1; i <= m; i++) if (f[lb[i][0]] != f[lb[i][1]])
{
    flj[f[lb[i][0]]].push_back(f[lb[i][1]]); ++rd[f[lb[i][1]]];
}
for (i = 1; i <= f[0]; i++) if (!rd[i]) dl[++wei] = i;
while (tou <= wei)
{
    x = dl[tou++]; g[x] += tv[x];
    for (i = 0; i < flj[x].size(); i++)
    {
        g[flj[x][i]] = max(g[flj[x][i]], g[x]);
        if (--rd[flj[x][i]] == 0) dl[++wei] = flj[x][i];
    }

        if (w == w1) return {w2, deeper(lca(u2, v1), lca(u2, v2)), w2};
        return {w2, w, w2};
    }
    return { };
}

```

5.6.3 换根树剖

本质是对普通树剖在换根后的子树进行分类讨论。

设预处理的根是 u ，当前根是 v ，那么 w 的子树如下：

1. $w = v$ ， dfn 区间为 $[1, n]$ 。
2. w 在 u, v 之间， dfn 区间为 $[1, n]$ 去掉 w 前往 v 方向的子树。找到这个子树的方法见 `find` 函数。
3. 其余情况， dfn 区间和原来一致。

```

int find(int x, int y) // 找到 y 向 x 的子树
{
    while ((top[x] != top[y]) && (f[top[x]] != y)) x = f[top[x]];
    if (top[x] == top[y]) return hc[y];
    return top[x];
}

```

$O(n + q \log n)$ ， $O(n)$ 。

5.6.4 毛毛虫剖分

毛毛虫剖分，一种由轻重链剖分（HLD）推广而成的树上结点重标号方法，支持修改 / 查询一只毛毛虫的信息，并且可以对毛毛虫的身体和足分别修改 / 查询不同信息。

严格强于树剖，而且复杂度和树剖一样哦！

一些定义（默认在一棵树上）：

毛毛虫：一条链和与这条链邻接的所有结点构成的集合。虫身（身体）：毛毛虫的链部分。虫足（足）：毛毛虫除虫身的部分。重标号方法首先重剖求出重链。DFS，若现在处理到结点 u ：若 u 还未被标号，则为其标号。若 u 是重链头，遍历这条重链，将邻接这条链的结点依次标号。先递归重儿子，再递归轻儿子。重标号性质对于重链，除链头外的结点标号连续。对于任意结点，其轻儿子标号连续。对于以重链头为根的子树，与这条重链邻接的所有结点标号连续。这样就可以随便维护毛毛虫信息了，顺便还能维护链信息，子树信息等。

时间复杂度同轻重链剖分。

以 SAM 为例，若我们只保留所有的转移边 (u, v) ，满足到达 u 的路径数目大于到达 v 的路径数目一半，且从 v 出发的路径数目大于从 u 出发的路径数目一半，这样剩余的子图显然会形成若干条链，且每个点恰好在一条链上。这样，我们容易证明，从根结点出发的任何一条路径，至多经过 $O(\log n)$ 条不在链上的转移边（也意味着至多经过 $O(\log n)$ 条链）。

以下是一段示例代码，展示了将一条链对应区间取出来的过程

```
vector<int> e[N];
vector<pair<int, int>> seg[N], qu[N];
int ans[Q];
int dfn[N], dep[N], nfd[N], top[N], f[N], sz[N], hc[N], pre[N], fir[N], lst2[N], rt[N];
int
void insert()
void dfs1(int u)
{
    sz[u] = 1;
    for (int v : e[u]) if (v != f[u])
    {
        dep[v] = dep[u] + 1;
        f[v] = u;
        dfs1(v);
        sz[u] += sz[v];
        if (sz[v] > sz[hc[u]]) hc[u] = v;
    }
    if (f[u]) erase(e[u], f[u]);
}
void dfs2(int u)

```

5.6.5 树上启发式合并, DSU on tree

一种过时的、基于两次 dfs 的写法，在复杂度要求不严时不如直接存储 set。

流程：

1. dfs 轻子树计算答案，并清空全局统计信息。
2. dfs 重子树统计答案和全局信息。

3. dfs 轻子树统计全局信息。

```

void dfs1(int x)
{
    siz[x]=zdep[x]=1;
    int i;
    for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x])
    {
        dep[lj[i]]=dep[f[lj[i]]=x]+1;
        dfs1(lj[i]);
        siz[x]+=siz[lj[i]];
        if (siz[hc[x]]<siz[lj[i]]) hc[x]=lj[i];
        zdep[x]=max(zdep[x],zdep[lj[i]]+1);
    }
}

void cal(int x)
{
    int i;
    dl[tou=wei=1]=x;
    while (tou<=wei)
    {
        ++dp[dep[x=dl[tou++]]];
        if ((dp[dep[x]]>dp[zd])||(dp[dep[x]]==dp[zd]&&(dep[x]<zd)) zd=dep[x];
        for (i=fir[x];i;i=nxt[i]) if (lj[i]!=f[x]) dl[++wei]=lj[i];
    }
}

void dfs2(int x)
{
    if (!hc[x])
    {
        if (++dp[dep[x]]>dp[zd]) zd=dep[x];
        return;
    }
    int i;
    for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x]))
    {
        dfs2(lj[i]);
        memset(dp+dep[lj[i]],0,zdep[lj[i]]<<2);
    }
    dfs2(hc[x]);
    dp[dep[x]]=1;
    if (dp[zd]<=1) zd=dep[x];
    for (i=fir[x];i;i=nxt[i]) if ((lj[i]!=f[x])&&(lj[i]!=hc[x])) cal(lj[i]);
    ans[x]=zd-dep[x];
}

```

5.6.6 长链剖分 (k 级祖先)

$O(n \log n + q)$, $O(n)$ 。

```

void dfs1(int x)
{
    int i;
    for (i = 1; i <= er[dep[x] - 1]; i++) f[x][i] = f[f[x][i - 1]][i - 1]; md[x] = dep[x];
    for (i = fir[x]; i; i = nxt[i]) { dep[lj[i]] = dep[x] + 1; dfs1(lj[i]); if (md[lj[i]] > md[dc[x]]) dc[x] = lj[i]; }
    if (dc[x]) md[x] = md[dc[x]];
}

```

```

}
void dfs2(int x)
{
    int i;
    if (dc[x])
    {
        top[dc[x]] = top[x];
        dfs2(dc[x]);
        for (i = fir[x]; i; i = nxt[i]) if (lj[i] != dc[x]) dfs2(top[lj[i]] = lj[i]);
    }
    if (x == top[x])
    {
        c = md[x] - dep[x]; y = x; up[x].push_back(x); down[x].push_back(x);
        for (i = 1; (i <= c) && (y = f[y][0]); i++) up[x].push_back(y); y = x;
        for (i = 1; i <= c; i++) down[x].push_back(y = dc[y]);
    }
}
int main()
{
    int n, q, ans = 0, x, y, c, i;
    ll ta = 0;
    cin >> n >> q >> s;
    for (i = 1; i <= n; i++) { cin >> f[i][0]; if (f[i][0] == 0) rt = i; else add(f[i][0], i); }
    for (i = 2; i <= n; i++) er[i] = er[i >> 1] + 1; dep[rt] = 1;
    dfs1(rt); dfs2(top[rt] = rt);
    for (i = 1; i <= q; i++)
    {
        x = (get(s) ^ ans) % n + 1; y = (get(s) ^ ans) % dep[x];
        //此时计算 x 的 y 级祖先。结果在 ans 中。
        if (y == 0) { ans = x; ta ^= (ll)i * ans; continue; }
        c = dep[x] - y; x = top[f[x][er[y]]];
        if (dep[x] > c) ans = up[x][dep[x] - c]; else ans = down[x][c - dep[x]];
        ta ^= (ll)i * ans;
    }
    cout << ta << endl;
}

```

5.6.7 长链剖分 (dp 合并)

一种常见的实现方法是用指针指向同一片数组区域，使得从链头到链尾正好指向连续的一段数组，就不需要计算偏移量了。

$O(n)$, $O(n)$ 。

```

void dfs1(int x)
{
    top[x]=1;
    for (int i=fir[x];i;i=nxt[i]) if (!top[lj[i]])
    {
        dfs1(lj[i]);
        if (len[lj[i]]>len[hc[x]]) hc[x]=lj[i];
    }
    len[x]=len[hc[x]]+1;top[hc[x]]=0;
}
void dfs2(int x)
{
    *f[x]=1;gs[x]=1;

```

```

if (!hc[x]) return;
ed[x]=1;f[hc[x]]=f[x]+1;
for (int i=fir[x];i;i=nxt[i]) if (!ed[lj[i]]) dfs2(lj[i]);
ans[x]=ans[hc[x]]+1;gs[x]=gs[hc[x]];
if (gs[x]==1) ans[x]=0;
for (int i=fir[x];i;i=nxt[i]) if ((!ed[lj[i]])&&(lj[i]!=hc[x]))
{
    int v=lj[i],*p;
    for (int j=0;j<len[v];j++)
    {
        *(p=f[x]+j+1)+=(f[v]+j);
        if (j+1==ans[x]) {gs[x]=*p;continue;}
        if ((*p>gs[x])||(*p==gs[x])&&(j+1<ans[x])) {gs[x]=*p;ans[x]=j+1;}
    }
}
gs[x]=*(f[x]+ans[x]);
ed[x]=0;
}

```

5.6.8 LCT

$O(n \log n)$, $O(n)$ 。

makeroot 会变根, split 会把 y 变根, findroot 会把根变根, link 会把 x, y 变根 (y 是新的), cut 会把 x, y 变根 (x 是新的), 注意 swap 子节点可能要 pushup。

代码为动态割边割点。

```

#include "bits/stdc++.h"
using namespace std;
template<class info, class tag> struct lct
{
    vector<array<int, 2>> c;
    vector<int> f, rev, lz, st;
    vector<info> s, v;
    vector<tag> tg;
#ifdef Rev
    vector<info> rs;
#endif
    lct(int n) :f(n + 1), c(n + 1), s(n + 1), v(n + 1), tg(n + 1), rev(n + 1), lz(n + 1), st(n + 1)
    {
#ifdef Rev
        , rs(n + 1)
#endif
    }
    bool nroot(int x) const
    {
        return c[f[x]][0] == x || c[f[x]][1] == x;
    }
    void pushup(int x)
    {
        int lc = c[x][0], rc = c[x][1];
        s[x] = v[x];
#ifdef Rev
        rs[x] = v[x];
#endif
        if (lc)

```

```

    {
        s[x] = s[lc] + s[x];

}

5.6.9 带子树的 LCT

$O(n \log n)$, $O(n)$ 。

你需要实现的是 `info` 类的 `+`, `+=`, `-=`。

1. `info` 维护的是从上往下的一条链以及这条链挂着的所有轻子树的信息。
2. `a+b` 表示两条链合并后的信息，其中 a 接近根。
3. `a+=b` 表示一条链合并了一个轻子树，即 b 是 a 链尾的子结点。
4. `a-=b` 表示一条链移除了一个轻子树，即 b 是 a 链尾的子节点。

如果有边权，将边 (u, v) 当成点并与 u, v 分别连边。

代码对应题意：

对于满足 $0 \leq e \leq N-2$ 的整数 e ，定义 $f_e(x) = b_e x + c_e$ 。

设 $e_0, e_1, \dots, e_k$ 为从顶点 x 到顶点 y 的简单路径上的边，按顺序排列，并定义

$$P(x, y) = f_{e_0}(f_{e_1}(\dots f_{e_k}(a_y) \dots)).$$

按给定顺序处理 Q 个查询。查询有两种类型：

- `0 w x r`：将 a_w 更新为 x ，然后输出

$$\left(\sum_{v=0}^{N-1} P(r, v) \right) \bmod 998244353.$$

- `1 e y z r`：将 (b_e, c_e) 更新为 (y, z) ，然后输出

$$\left(\sum_{v=0}^{N-1} P(r, v) \right) \bmod 998244353.$$

```

}

```

5.6.12 虚树

传入点标号列表，返回虚树边表。自动认为 1 是根，标号从 1 开始。

需要注意的是：在清空的时候需要同时考虑点列表和边表，都清空一下。

你需要提供的是：dep, lca, dfn。

$O(n + \sum k \log n)$, $O(n)$ 。

```

vector<pair<int, int>> get_tree(vector<int> a)
{
    vector<pair<int, int>> edges;
    sort(all(a), [&](int u, int v) { return dfn[u] < dfn[v]; });
    vector<int> st(a.size() + 2);
    int tp = 0;
    auto ins = [&](int u) {

```

```

    if (tp == 0)
    {
        st[tp = 1] = u;
        return;
    }
    int v = lca(st[tp], u);
    while (tp > 1 && dep[v] < dep[st[tp - 1]])
    {
        edges.emplace_back(st[tp - 1], st[tp]);
        --tp;
    }
    if (dep[v] < dep[st[tp]]) edges.emplace_back(v, st[tp--]);
    if (!tp || st[tp] != v) st[++tp] = v;
    st[++tp] = u;
};
if (a[0] != 1) st[tp = 1] = 1; //先行添加根节点
for (int u : a) ins(u);
if (tp) while (--tp) edges.emplace_back(st[tp], st[tp + 1]); //回溯
return edges;
}

```

5.6.13 点分治

点分治板子的参考意义不大。

$O(n \log n)$, $O(n)$ 。

```

int siz[N], dep[N];
int n, ksiz, md, rt, mn;
bool ed[N];
void find(int u)
{
    ed[u] = 1; siz[u] = 1;
    int mx = 0;
    for (int v : e[u]) if (!ed[v])
    {
        find(v);
        siz[u] += siz[v];
        mx = max(mx, siz[v]);
    }
    mx = max(mx, ksiz - siz[u]);
    if (mn > mx) mn = mx, rt = u;
    ed[u] = 0;
}
void cal(int u)
{
    md = max(md, dep[u]);
    ed[u] = 1; ++cnt[dep[u]];
    for (int v : e[u]) if (!ed[v])
    {
        dep[v] = dep[u] + 1;
        cal(v);
    }
    ed[u] = 0;
}
void solve(int u)
{
    mn = 1e9;
}

```

```

find(u);
ed[rt] = 1;
vector<int> c;
for (int v : e[rt]) if (!ed[v])
{
    c.push_back(v);
    if (siz[v] >= siz[rt]) siz[v] = siz[u] - siz[rt];
}
sort(all(c), [&](const int &a, const int &b) {return siz[a] < siz[b]; });
NTT::Q a(vector<ui>{1});
NT::Q b(vector<ui>{1});
for (int v : c)
{
    md = 0; dep[v] = 1;
    cal(v); ++md;
    vector<ui> d(cnt, cnt + md);
    NTT::Q e(d);
    NT::Q f(d);
    auto g = e & a;
    auto h = f & b;
    for (int i = 0; i < g.a.size(); i++) r1[i] = (r1[i] + g.a[i]) % NTT::p;
    for (int i = 0; i < h.a.size(); i++) r2[i] = (r2[i] + h.a[i]) % NT::p;
    a += e; b += f;
    fill_n(cnt, md, 0);
}
for (int v : c)
{
    ksiz = siz[v];
    solve(v);
}
}

```

5.6.14 点分树

核心结论：点分树上 lca 出现在原树路径上。

$O(n \log^2 n)$, $O(n \log n)$ 。

```

template<class typC> struct bit
{
    vector<typC> a;
    int n;
    bit() { }
    bit(int nn) : n(nn), a(nn + 1) { }
    template<class T> bit(int nn, T *b) : n(nn), a(nn + 1)
    {
        for (int i = 1; i <= n; i++) a[i] = b[i - 1];
        for (int i = 1; i <= n; i++) if (i + (i & -i) <= n) a[i + (i & -i)] += a[i];
    }
    void add(int x, typC y)
    {
        //cerr<<"add "<<x<<" by "<<y<<endl;
        ++x;
        x = clamp(x, 1, n + 1);
        if (x > n) return;
        assert(1 <= x && x <= n);
        a[x] += y;
        while ((x += x & -x) <= n) a[x] += y;
    }
};

```

```

}

```

5.7.3 回路计数 (BEST 定理) /生成树计数

$O(n^3)$, $O(n^2)$ 。

以 u 为起点的欧拉回路个数 $sum = T(u) \times \prod_{v=1}^n (out(v) - 1)!$, 其中 $T(u)$ 是以 u 为根的内向树个数 (出度矩阵-邻接矩阵), $out(v)$ 是 v 的出度。若允许循环同构 (如 $1 \rightarrow 2 \rightarrow 1 \rightarrow 3 \rightarrow 1$ 与 $1 \rightarrow 3 \rightarrow 1 \rightarrow 2 \rightarrow 1$), 还需多乘 $out(u)$ 。

这里的部分代码是未经验证的。

```
ull det(vector<vector<ull>> b)
{
    ull r=1;
    int n=b.size(), i, j, k;
    for (i=0; i<n; i++)
    {
        for (j=i; j<n; j++) if (b[j][i]) break;
        if (j==n) return 0;
        swap(b[j], b[i]);
        if (j!=i) r=(p-r)%p;
        r=r*b[i][i]%p;

```

5.8 三/四元环计数

不能处理有重边和自环的情况。

$O(m\sqrt{m})$, $O(n+m)$ 。

注意四元环数的是边四元环。点四元环需要去掉四点完全图个数 *2, 似乎不太能做?

三元环是可以枚举的, 你可以在 ans 改变时记录三元环 (i, u, v) 。

```

ll triple(const vector<pair<int, int>> &edges) //start from 0
{
    int n = 0, i;
    for (auto [u, v] : edges) n = max({n, u, v});
    ++n;
    vector<int> d(n), id(n), rk(n), cnt(n);
    vector<vector<int>>> e(n);
    for (auto [u, v] : edges) ++d[u], ++d[v];
    iota(all(id), 0); sort(all(id), [&](int x, int y) { return d[x] < d[y]; });
    for (i = 0; i < n; i++) rk[id[i]] = i;
    for (auto [u, v] : edges)
    {
        if (rk[u] > rk[v]) swap(u, v);
        e[u].push_back(v);
    }
    ll ans = 0;
    for (i = 0; i < n; i++)
    {
        for (int u : e[i]) cnt[u] = 1;
        for (int u : e[i]) for (int v : e[u]) ans += cnt[v];
        for (int u : e[i]) cnt[u] = 0;
    }
    return ans;
}

ll quadruple(const vector<pair<int, int>> &edges)
{
    int n = 0, i;
    for (auto [u, v] : edges) n = max({n, u, v});
    ++n;
    vector<int> d(n), id(n), rk(n), cnt(n);
    vector<vector<int>>> e(n), lk(n);

```

```

for (auto [u, v] : edges) ++d[u], ++d[v];
iota(all(id), 0); sort(all(id), [&](int x, int y) { return d[x] < d[y]; });
for (i = 0; i < n; i++) rk[id[i]] = i;
for (auto [u, v] : edges)
{
    if (rk[u] > rk[v]) swap(u, v);
    e[u].push_back(v);
    lk[u].push_back(v);
    lk[v].push_back(u);
}
ll ans = 0;
for (i = 0; i < n; i++)

```

5.10 prufer 与树的互相转化

$O(n)$, $O(n)$ 。

```

vector<int> edges_to_prufer(const vector<pair<int, int>> &eg) //[1,n], 定根为 n
{
    int n = eg.size() + 1, i, j, k;
    vector<int> fir(n + 1), nxt(n * 2 + 1), e(n * 2 + 1), rd(n + 1);
    int cnt = 0;

```

```

for (auto [u, v] : eg)
{
    e[++cnt] = v; nxt[cnt] = fir[u]; fir[u] = cnt; ++rd[v];
    e[++cnt] = u; nxt[cnt] = fir[v]; fir[v] = cnt; ++rd[u];
}
for (i = 1; i <= n; i++) if (rd[i] == 1) break;
int u = i;
vector<int> r; r.reserve(n - 2);
for (j = 1; j < n - 1; j++)
{
    for (k = fir[u], u = rd[u] = 0; k; k = nxt[k]) if (rd[e[k]])
    {
        r.push_back(e[k]);
        if ((--rd[e[k]] == 1) && (e[k] < i)) u = e[k];
    }
    if (!u) { while (rd[i] != 1) ++i; u = i; }
}
return r;
}
vector<pair<int, int>> prufer_to_edges(const vector<int> &p)//[1,n], 定根为 n
{
    int n = p.size(), i, j, k;
    int m = n + 3;
    vector<int> cs(m);
    for (i = 0; i < n; i++) ++cs[p[i]];
    i = 0;
    while (cs[++i]);
    int u = i, v;
    vector<pair<int, int>> r;
    r.reserve(n - 2);
    for (j = 0; j < n; j++)
    {
        cs[u] = 1e9;
        r.push_back({u, v = p[j]});

    }
    r.push_back({u, n + 2});
    return r;
}

```

5.11 最小密度环

求所有环中边权和除以边数最少的, $O(nm)$ 。更常用的做法是二分 spfa。

```

#include "bits/stdc++.h"
using namespace std;
const int N=3e3+5,M=1e4+5;
const double inf=1e18;
int u[M],v[M];
double f[N][N],w[M];
int main()
{
    ios::sync_with_stdio(0);cin.tie(0);
    cout<<setiosflags(ios::fixed)<<setprecision(8);
    int n,m,i,j;
    cin>>n>>m;

```

```

for (i=1;i<=m;i++) cin>>u[i]>>v[i]>>w[i];
++n;
for (i=1;i<=n;i++)
{
    fill_n(f[i]+1,n,inf);
    for (j=1;j<=m;j++) f[i][v[j]]=min(f[i][v[j]],f[i-1][u[j]]+w[j]);
}
double ans=inf;
for (i=1;i<=n;i++) if (f[n][i]!=inf)
{
    double r=-inf;
    for (j=1;j<=n;j++) r=max(r,(f[n][i]-f[j][i])/(n-j));
    ans=min(ans,r);
}
cout<<ans<<endl;
}

```

5.12 点染色

结论: $\chi(G) \leq \Delta(G) + 1$, 其中 $\Delta(G)$ 是图的最大度。只有奇圈和完全图取等。
构造方案只能爆搜。

```

vector<int> chromatic_number(int n,const vector<pair<int,int>> &edges)//[0,n)
{
    vector r(n,-1),cur(n,-1);
    vector<vector<int>> e(n);
    int ans=0,i;
    for (auto [u,v]:edges) e[u].push_back(v),e[v].push_back(u);
    for (i=0;i<=n;i++) ans=max(ans,(int)e[i].size());
    ans+=2;
    vector p(n,vector(ans,0));
    function<void(int)> dfs=[&](int u)
    {
        int col=u?*max_element(cur.begin(),cur.begin()+u)+1:0;
        if (col>=ans) return;
        if (u==n)
        {
            r=cur;
            ans=col;
            return;
        }
        int i;
        for (int i=0;i<=col;i++) if (!p[u][i])
        {
            cur[u]=i;
            for (int v:e[u]) ++p[v][i];
            dfs(u+1);
            for (int v:e[u]) --p[v][i];
        }
    };
    dfs(0);
    return r;
}

```

5.13 最大独立集

爆搜。

```
vector<int> indep_set(int n,const vector<pair<int,int>> &edges)//[0,n)
{
    vector<vector<int>> e(n);
    mt19937 rnd(998);
    vector<int> p(n),q(n),ed(n);
    iota(all(p),0);
    shuffle(all(p),rnd);
    for (int i=0;i<n;i++) q[p[i]]=i;
    for (auto [u,v]:edges)
    {
        e[p[u]].push_back(p[v]);
        e[p[v]].push_back(p[u]);
    }
    vector<int> r,cur;
    function<void(int)> dfs=[&](int u)
    {
        if (cur.size()+n-u<=r.size()) return;
        if (u==n)
        {
            r=cur;
            return;
        }
        if (!ed[u])
        {
            cur.push_back(u);
            for (int v:e[u]) ++ed[v];
            dfs(u+1);
            for (int v:e[u]) --ed[v];
            cur.pop_back();
        }
        if (ed[u]||e[u].size()) dfs(u+1);
    };dfs(0);
    for (int &x:r) x=q[x];
    sort(all(r));
    return r;
}
```

5.14 弦图

单纯点： v 和 v 邻点构成团。

完美消除序列： v_i 在 $\{v_i, v_{i+1}, \dots, v_n\}$ 为单纯点。

$N(v_i) = \{v_j | j > i \wedge (v_i, v_j) \in E\}$, $next(v_i)$ 为 $N(v_i)$ 最靠前的点。

极大团一定是 $\{v\} \cup N(v)$ 。

最大团大小等于色数。

弦图判定：等价于是否存在完美消除序列。首先求出一个完美消除序列，然后判定是否合法。

判定方法：设 $v_{i+1}, \dots, v_n$ 中与 v_i 相邻的依次为 $v'_1, \dots, v'_m$ 。只需判断是否 v'_1 与 $v'_2, \dots, v'_m$ 相邻。

LexBFS 算法（我不会写）

每个点有一个字符串 label，初始为 0。从 $i = n$ 到 $i = 1$ 确定，选 label 字典序最大的 u ，再把 u 邻点的 label 后面接一个 i 。

最大势算法：从 v_n 求到 v_1 ，设 $label_i$ 表示 i 与多少个已选点相邻，每次选 $label_i$ 最大的点。

弦图极大团： $\{v|\forall next(w)=v, |N(v)| \geq |N(w)|\}$ 。选出的集合为基本点，按上述极大团构造。

弦图染色：从 v_n 到 v_1 依次选最小可染的色。

最大独立集：从 v_1 到 v_n 能选就选。

最小团覆盖：设最大独立集为 $\{p_m\}$ ，最小团覆盖为 $\{\{p_i\} \cup N(p_i)\}$ 。

区间图：两个区间有边当且仅当交集非空。

区间图是弦图。

代码如下：

```
namespace chordal_graph//下标从 1 开始
{
    const int N=1e5+2;//点数
    bool ed[N];
    vector<int> e[N];
    int n;

6 计算几何

6.1 自适应 simpson 法

$\text{sim}(l,r)$ 计算 $\int_l^r f(x) dx$

```
const db eps=1e-7;
db sl,sr,sm,a;
db f(db x)
{
    return pow(x,a/x-x);
}
db g(db l,db r)
{
    db mid=(l+r)*0.5;
    return (f(l)+f(r)+f(mid)*4)/6*(r-l);
}
db sim(db l,db r)
{
    db mid=(l+r)*0.5;
    sl=g(l,mid);sr=g(mid,r);sm=g(l,r);
    if (abs(sl+sr-sm)<eps) return sl+sr;
    return sim(l,mid)+sim(mid,r);
}
```

6.2 计算几何全

功能其实比较少，因为实际遇到的几何题不多。最有用的可能是闵可夫斯基和合并凸包，和常规的线段判交之类的。其余功能最好直接使用 HDU 板。

```
namespace geo
{
#define tpl template<class T>
    using ll = long long;
    using lll = __int128;
    using db = long double;
    tpl using up = conditional_t<std::is_same_v<T, ll>, lll,
        conditional_t<std::is_same_v<T, db>, db, void>>;
    const db eps = 1e-7, pi = 3.1415926535897932384626434;
#define all(x) (x).begin(),(x).end()
    inline int sgn(const ll &x) { return x < 0 ? -1 : (x > 0); }
    inline int sgn(const lll &x) { return x < 0 ? -1 : (x > 0); }
    inline int sgn(const db &x)
    {
        if (abs(x) < eps) return 0;
        return x > 0 ? 1 : -1;
    }
    tpl struct vec/* 为叉乘, dot 为点乘, 只允许使用 long double 和 ll */
    {

```

另附一份支持二分斜率的代码。这里维护的是 (x, y) ，其中 $y = C + x^2$ ，因此 x 整体增加会影响 y 。

```

bool FLAG = 0;
ll K;
struct Q
{
    ll x;
    mutable ll y;
    mutable decltype(set<Q>().begin()) r;
    Q operator-(const Q &o) const { return {x - o.x, y - o.y}; }
    lll operator*(const Q &o) const
    {
        return (lll)x * o.y - (lll)y * o.x;
    }
};
set<Q>::iterator END;
bool operator<(const Q &a, const Q &b)
{
    if (FLAG)
    {
        assert(b.x == 0 && b.y == 0);
        if (a.r == END) return 0;
        return (lll)a.x * K + a.y < (lll)a.r->x * K + a.r->y;
    }
    return a.x < b.x;
}
struct convex
{
    set<Q> s;
    ll tagx = 0, tagy = 0;
    void check(auto it)
    {
        decltype(it) jt, kt;
        if (it != s.begin())
        {
            jt = prev(it);
            if (jt != s.begin())
            {
                kt = prev(jt);
                while ((*it - *kt) * (*jt - *kt) <= 0)

```

```

        {

    FLAG = 0;
    return k * (it->x + tagx) + it->y + tagy - tagx * tagx;
}

void fun(ll &x, ll &y) const
{
    y -= x * x;
    x += tagx;
    y += tagy + x * x;
}
};

```

7 杂项

7.1 枚举大小为 k 的集合

思路：通过进位创造 1，再把一串 1 移到最后。

```
for (int s=(1<<k)-1,t;s<1<<n;t=s+(s&-s),s=(s&~t)>>__lg(s&-s)+1|t)
{}

```

7.2 min plus 卷积

计算 $c_i = \min_{j=0}^i a_j + b_{i-j}$ 。

要求 b 是凸的，即 $b_{i+1} - b_i$ 不降。

```
template <class T> vector<T> min_plus_convolution(const vector<T> &a, const vector<T> &b)
{
    int n = a.size(), m = b.size(), i;
    vector<T> c(n + m - 1);
    function<void(int, int, int, int)> dfs = [&](int l, int r, int ql, int qr) {
        if (l > r) return;
        int mid = l + r >> 1;
        while (ql + m <= l) ++ql;
        while (qr > r) --qr;
        int qmid = -1;
        c[mid] = inf;
        for (int i = ql; i <= qr; i++) if (mid - i >= 0 && mid - i < m && cmin(c[mid], a[i] + b[
mid - i])) qmid = i;
        dfs(l, mid - 1, ql, qmid);
        dfs(mid + 1, r, qmid, qr);
    };
    dfs(0, n + m - 2, 0, n - 1);
    return c;
}

```

7.3 所有区间 GCD

需要自定义 fun，如 gcd，and，or。

```
template<class T> struct GCD
{
    vector<pair<int, T>> res;
    GCD(const vector<T> &a) :res(n)
    {
        int n = a.size(), i, j;
        vector<ll> v(n);
        vector<int> l(n);
        for (i = 0; i < n; i++)
        {
            for (v[i] = a[i], j = l[i] = i; j >= 0; j = l[j] - 1)
            {
                v[j] = fun(v[j], a[i]);
                while (l[j] && fun(a[i], v[l[j] - 1]) == fun(a[i], v[j])) l[j] = l[l[j] - 1];
                // [l[j]..j,i] 区间内的值求 fun 均为 v[j]
            }
        }
    }
}

```

```

    }
};

```

7.4 整体二分（区间 k -th）

$O((n+q)\log a)$, $O(n+q)$ 。

```

struct cz
{
    int x, y, kth, pos, typ;
};
cz q[M], st1[M], st2[M];
int a[N], b[N], d[N], ans[N], s[N];
int n, m, t1, t2, i, j, c, gs;
void add(int x, int y)
{
    for (; x <= n; x += x & -x) s[x] += y;
}
int sum(int x)
{
    int ans = 0;
    for (; x; x -= x & -x) ans += s[x];
    return ans;
}
void ztef(int ql, int qr, int l, int r)
{
    if (ql > qr) return;
    int mid = l + r >> 1, i, midd;
    t1 = t2 = 0;
    if (l == r)
    {
        for (i = ql; i <= qr; i++) if (q[i].typ) ans[q[i].pos] = d[l];
        return;
    }
    for (i = ql; i <= qr; i++) if (q[i].typ)
    {
        midd = sum(q[i].y) - sum(q[i].x - 1);
        if (midd >= q[i].kth) st1[++t1] = q[i]; else
        {
            st2[++t2] = q[i];
            st2[t2].kth -= midd;
        }
    }
    else if (q[i].pos <= mid)
    {
        add(q[i].x, 1);
        st1[++t1] = q[i];
    }
    else st2[++t2] = q[i];
    for (i = 1; i <= t1; i++) if (!st1[i].typ) add(st1[i].x, -1);
    for (i = 1; i <= t1; i++) q[i + ql - 1] = st1[i];
    midd = ql + t1 - 1;
    for (i = 1; i <= t2; i++) q[i + midd] = st2[i];
    ztef(ql, midd, l, mid); ztef(midd + 1, qr, mid + 1, r);
}
int main()
{

```

```

cin >> n >> m;
for (i = 1; i <= n; i++)
{
    cin >> a[i];
    b[i] = a[i];
}
sort(b + 1, b + n + 1);
d[gs = 1] = b[1];
for (i = 2; i <= n; i++) if (b[i] != b[i - 1]) d[++gs] = b[i];
for (i = 1; i <= n; i++) a[i] = lower_bound(d + 1, d + gs + 1, a[i]) - d;
for (i = 1; i <= n; i++)
{
    q[i].x = i; q[i].pos = a[i]; q[i].typ = 0;
}
for (i = 1; i <= m; i++)
{
    cin >> q[i + n].x >> q[i + n].y >> q[i + n].kth;
    q[i + n].pos = i; q[i + n].typ = 1;
}
ztef(1, n + m, 1, gs);
for (i = 1; i <= m; i++) printf("%d\n", ans[i]);
}

```

7.5 高精度

除法和取模有点问题，但 gcd 是对的。

```

7.6 分散层叠算法 (Fractional Cascading)

$O(n + q(k + \log n))$, $O(n)$ 。

给出 k 个长度为 n 的有序数组。

现在有 q 个查询：给出数 x ，分别求出每个数组中大于等于 x 的最小的数（非严格后继）。

若后继不存在，则定义为 0。你需要在线地回答这些询问。

```
int a[M][N], b[M][N << 1], c[M][N << 1][2], len[M], ans[M];
int n, m, qs, p, q, d, i, j, x, y, la;
int main()
{
    cin >> n >> m >> qs >> d;
    for (j = 1; j <= m; j++) for (i = 0; i < n; i++) cin >> a[j][i];
    for (j = 1; j <= m; j++) a[j][n] = inf + j; ++n;
    for (i = 0; i < n; i++) b[m][i] = a[m][i], c[m][i][0] = i;
    len[m] = n;
    for (j = m - 1; j; j--)
    {
        p = 0, q = 1;
        while (p < n && q < len[j + 1])
            if (a[j][p] < b[j + 1][q]) b[j][len[j]] = a[j][p], c[j][len[j]][0] = p++, c[j][len[j]
            ]++[1] = q;
            else b[j][len[j]] = b[j + 1][q], c[j][len[j]][0] = p, c[j][len[j]++][1] = q, q += 2;
        while (p < n) b[j][len[j]] = a[j][p], c[j][len[j]][0] = p++, c[j][len[j]++][1] = q;
        while (q < len[j + 1]) b[j][len[j]] = b[j + 1][q], c[j][len[j]][0] = p, c[j][len[j]++][1]
        = q, q += 2;
    }
    for (int ii = 1; ii <= qs; ii++)
    {
        cin >> x; x ^= la;
        y = lower_bound(b[1], b[1] + len[1], x) - b[1];
        ans[1] = a[1][c[1][y][0]]; y = c[1][y][1]; // 下标是 c[1][y][0]
        for (j = 2; j <= m; j++)
        {
            if (y && b[j][y - 1] >= x) --y;
            ans[j] = a[j][c[j][y][0]]; // 下标是 c[j][y][0]
            y = c[j][y][1];
        }
        la = 0;
        for (i = 1; i <= m; i++) la ^= ans[i] > inf ? 0 : ans[i];
        if (ii % d == 0) cout << la << '\n';
    }
}
```

7.7 圆上整点 (二平方和定理)

$x^2 + y^2 = n$ 的整数解的数目的四分之一 $f(n)$ 是积性数论函数，且对于素数幂有： $f(p^k) =$

$$\begin{cases} 1 & p = 2 \\ k + 1 & p \equiv 1 \pmod{4} \\ (k + 1) \bmod 2 & p \equiv 3 \pmod{4} \end{cases}$$

以下代码给出所有的非负整数解。注意非负整数解个数不等于 $f(n)$ 。

时间复杂度为 $O(n^{\frac{1}{4}} + f(n))$ ，其中 $O(n^{\frac{1}{4}})$ 是 pollard-rho 的复杂度。

$f(n)$ 的量级不好分析，但不会超过约数个数 $O(d(n)) \approx O(n^{\frac{1}{3}})$ ，且可以推测不能达到。实践上 10^{18} 以内 $f(n) \leq 3072$ 。

        for (int i = 0; s[i]; ++i) _putchar(s[i]); return *this;
    }
}fio;

```

7.11 手动开栈

一种写法是文件开头放，但部分 OJ 会失效。

```
#pragma comment(linker, "/STACK:102400000,102400000")
```

另一种写法是在 main 开头写，但必须以 `exit(0)` 结束程序。
以下两个应该有一个是对的，不对会 CE。

```

{
    static int OP = 0;
    if (OP++ == 0)
    {
        int size = 256 << 20; // 256MB
        char *p = (char *)malloc(size) + size;
        __asm__ ("movl 0, %%esp\n" :: "r"(p));
    }
}
{
    static int OP = 0;
    if (OP++ == 0)
    {
        int size = 128 << 20; // 128MB
        char *p = new char[size] + size;
        __asm__ __volatile__ ("movq 0, %%rsp\n" "pushq $exit\n" "jmp _main\n" :: "r"(p));
    }
}
}

```

7.12 德扑

solve 返回按照出现次数排序的 `vector<int>` (0 下标处为牌型), 这样就可以字典序比较了。

```

struct Q
{
    int suit, rank;
    bool operator<(const Q &o) const { return pair{rank, suit} < pair{o.rank, o.suit}; }
    bool operator==(const Q &o) const { return pair{rank, suit} == pair{o.rank, o.suit}; }
};
auto solve = [&](vector<Q> a) {
    vector<int> res;
    vector<int> cnt(15);
    for (auto [s, r] : a) ++cnt[r];
    sort(all(a));
    int i;
    bool is_flush = 1, is_str = 0;
    for (i = 1; i < 5; i++) is_flush &= a[i].suit == a[0].suit;
    is_str = *max_element(all(cnt)) == 1 && a[0].rank + 4 == a[4].rank;
    vector<int> b(6);
    for (i = 1; i < 6; i++) b[i] = a[i - 1].rank;
    sort(1 + all(b), [&](int x, int y) {
        return pair{cnt[x], x} > pair{cnt[y], y};
    });
    if (b == vector{0, 12, 3, 2, 1, 0}) is_str = 1, b[1] = 0;
    if (is_flush && is_str) return b[0] = 9, b;
    if (cnt[b[1]] == 4) return b[0] = 8, b;
    if (cnt[b[1]] == 3 && cnt[b[4]] == 2) return b[0] = 7, b;
    if (is_flush) return b[0] = 6, b;
    if (is_str) return b[0] = 5, b;
    if (cnt[b[1]] == 3) return b[0] = 4, b;
    if (cnt[b[1]] == 2 && cnt[b[3]] == 2) return b[0] = 3, b;
    if (cnt[b[1]] == 2) return b[0] = 2, b;
    return b;
};
auto turn = [&](string s) {
    Q res = Q{"SHDC".find(s[0]), "23456789TJQKA".find(s[1])};
}

```

```
    return res;
};
```

7.13 随机函数

u64 → u64

```
ull rnd(ull x = 0)
{
    static ull s = chrono::high_resolution_clock::now().time_since_epoch().count() ^ 0
    x9e3779b97f4a7c15;
    s += 0x60bee2bee120fc15;
    x ^= s ^ 0xa0761d6478bd642f;
    ulll m = (ulll)x * (x ^ 0xe7037ed1a0b428db);
    return (ull)m ^ (ull)(m >> 64);
}
```

7.14 约数个数表

7.16 公式

向上取整的整除分块 $[i, \lfloor \frac{n-1}{\lceil \frac{n}{i} \rceil - 1} \rfloor]$

n 个点 k 个连通块的生成树方案 $n^{k-2} \prod_{i=1}^k \text{siz}_i$

(x, y) 曼哈顿距离 $\rightarrow (x+y, x-y)$ 切比雪夫距离

(x, y) 切比雪夫距离 $\rightarrow (\frac{x+y}{2}, \frac{x-y}{2})$ 曼哈顿距离

Kummer's Theorem: $\binom{n+m}{n}$ 含 p ($p \in \text{prime}$) 的次数是 $n+m$ 在 p 进制下的进位数

$$\ln(1-x^V) = -\sum_{i \geq 1} \frac{x^{Vi}}{i}$$

$$x^{\bar{n}} = \sum_i S_1(n, i) x^i$$

$$\begin{cases} x \equiv a_1 \pmod{m_1} \\ x \equiv a_2 \pmod{m_2} \\ \dots \\ x \equiv a_n \pmod{m_n} \end{cases}$$

$V - E + F = 2$, $S = n + \frac{s}{2} - 1$. (n 为内部, s 为边上)

用途: 对于相邻的不相等的值, 在中间画一条线 (最外也画), 连通块个数 $= 1 + E - V +$ 内部框个数

注意全都是不含矩形边界上的。

卡特兰三角: 由 n 个 -1 和 m 个 1 组成一个序列, 满足所有前缀和小于 k 的方案数 ($k \leq m \leq n+k-1$): $\binom{n+m}{m} - \binom{n+m}{m-k}$

贝尔数 (划分集合方案数) EGF: $\exp(e^x - 1)$, $B_n = \sum_{i=0}^n S_2(n, i)$, 伯努利数 EGF: $\frac{x}{e^x - 1}$

$$S_1(i, m) \text{ EGF: } \frac{(\sum_{i \geq 0} \frac{x^i}{i})^m}{m!}, S_2(i, m) \text{ EGF: } \frac{(e^x - 1)^m}{m!}. S_2(n, m) = [x^n] x^m (\prod_{i=1}^m (1 - ix))^{-1}, S_2(n, m) \equiv [n - m \& \lfloor \frac{m-1}{2} \rfloor = 0] \pmod{2}.$$

多项式牛顿迭代: 如果已知 $G(F(x)) \equiv 0 \pmod{x^{2n}}$, $G(F_*(x)) \equiv 0 \pmod{x^n}$, 则有 $F(x) \equiv F_*(x) - \frac{G(F_*(x))}{G'(F_*(x))} \pmod{x^{2n}}$. 求导时孤立的多项式视为常数。

$$\int_0^1 t^a (1-t)^b dt = \frac{a!b!}{(a+b+1)!}, \sum_{i=0}^{n-1} i^k = \frac{n^{k+1}}{k+1}$$

Burnside 引理: 等价类数量为 $\sum_{g \in G} \frac{X^g}{|G|}$, X^g 表示 g 变换下不动点的数量。

Polya 定理: 染色方案数为 $\sum_{g \in G} \frac{m^{c(g)}}{|G|}$, 其中 $c(g)$ 表示 g 变换下环的数量。

假设已经只保留了一个牛人酋长, 其名字为 $A = a_1 a_2 \cdots a_l$ 。

假设王国旁边开了一座赌场, 每单位时间 (就称为“秒”吧) 会有一个赌徒带着 1 铜币进入赌场。

赌场规则很简单: 支付 x 铜币赌下一秒会唱出 y , 如果猜对了就返还 nx 铜币, 否则钱就没了。

每个赌徒会如下行动: 支付 1 铜币赌下一秒会唱出 a_1 , 如果赌对了就支付得到的 n 铜币赌下一秒会唱出 a_2 , 如果还对了就支付得到的 n^2 铜币赌下一秒会唱出 a_3 , 等等, 以此类推, 最后支付 n^{l-1} 铜币赌下一秒会唱出 a_l 。

一旦连续唱出了 $a_1 a_2 \cdots a_l$, 赌场老板就会认为自己亏大了而关门, 并驱散所有赌徒。

那么关门前发生了什么呢? 以 $A = \{1, 4, 1, 5, 1, 1, 4, 1\}$, $n = 5$ 为例:

- 最后一位赌徒拿着 5 铜币离开; - 倒数第三位赌徒拿着 5^3 铜币离开; - 倒数第八位赌徒拿着 5^8 铜币离开; - 其他所有赌徒空手而归。

我们可以发现 1, 3 恰好是原序列的所有 border 的长度, 而且对于其他的名字也有这样的规律。

这时候最神奇的一步来了: 由于这个赌博游戏是公平的, 因此赌场应该期望下不赚不赔, 因此关门时期望来了 $5 + 5^3 + 5^8$ 个赌徒, 因此期望需要 $5 + 5^3 + 5^8$ 单位时间唱出这个名字。

同理，即可知道对于一般的 A ，答案为：

$$\sum_{a_1 a_2 \cdots a_c = a_{l-c+1} a_{l-c+2} \cdots a_l} n^c$$

8 语言基础

8.1 Makefile

```
%:%.cpp %.in
    g++ $< -o $@ -std=c++20 -DLOCAL -D_GLIBCXX_DEBUG -D_GLIBCXX_DEBUG_PEDANTIC -fsanitize=
    undefined
    ./$@ < $@.in
```

8.2 debug.h

```
template <class T, size_t size = tuple_size<T>::value> string to_dbg(T, string s = "") requires(
    not ranges::range<T>);
string to_dbg(auto x) requires requires(ostream &os) { os << x; }
{
    ostringstream os;
    os << x;
    return os.str();
}
string to_dbg(ranges::range auto x, string s = "") requires(not is_same_v<decltype(x), string>)
{
    for (auto xi : x) s += ", " + to_dbg(xi);
    return "[" + s.substr(2 * !!s.size()) + "]";
}
template <class T, size_t size> string to_dbg(T x, string s) requires(not ranges::range<T>)
{
    [&] <size_t... I>(index_sequence<I...>) { ((s += ", " + to_dbg(get<I>(x))), ...); } (
    make_index_sequence<size>());
    return "(" + s.substr(2 * !!s.size()) + ")";
}
#define dbg(...) cerr << __LINE__ << ": " #__VA_ARGS__ " " << to_dbg(tuple(__VA_ARGS__)) << "
    \n"
```

8.3 初始代码

```
#include "bits/stdc++.h"
using namespace std;
using ll = long long;
#define all(x) (x).begin(), (x).end()
int main()
{
    ios::sync_with_stdio(0); cin.tie(0);
}
```

抄写完 debug.h 后，补充于 using namespace std; 下一行：

```
#ifdef LOCAL
#include "debug.h"
#endif
```

8.4 bitset

```

#include "bits/stdc++.h"
using namespace std;
bitset<10> f(12);
char s2[] = "100101";
bitset<10> g(s2);
string s = "100101";//reverse 了
bitset<10> h(s);
int main()
{
    for (int i = 0; i <= 9; i++) cout << f.test(i); cout << endl;
    for (int i = 0; i <= 9; i++) cout << g.test(i); cout << endl;
    for (int i = 0; i <= 9; i++) cout << h.test(i); cout << endl;
    cout << h << endl;
    foo.count();//1的个数
    foo.flip();//全部翻转
    foo.set();//变1
    foo.reset();//变0
    foo.to_string();
    foo.to_ulong();
    foo.to_ullong();
    foo._Find_first();
    foo._Find_next();
    //位运算: << 变大, >> 变小
}

```

输出:

```

0011000000
1010010000
1010010000
0000100101

```

8.5 pb_ds 和一些奇怪的用法

```

#pragma GCC optimize("Ofast")

```

8.6 python 使用方法

注意事项: python 容易爆栈, 且引用与赋值较为混乱。注意局部变量的 global 怎么写 (如果需要修改全局内容)。

文件操作

```

fi = open("discuss.in", "r")
fo = open("discuss.out", "w")
n = int(fi.readline())
fo.write(str(ans))

```

类的构造, 重载运算符

```

class Q:
    def __init__(self, x, y):
        self.x = x
        self.y = y

    def __add__(self, o):
        r = Q(self.x + o.x, self.y + o.y)
        return r

    def __sub__(self, o):
        r = Q(self.x - o.x, self.y - o.y)
        return r

    def __mul__(self, o):
        return self.x * o.y - self.y * o.x

    def __lt__(self, o):
        if self.x != o.x:

```

```

        return self.x < o.x
    return self.y < o.y

n, m = map(int, input().split())
c = list(map(int, input().split()))
print(*c)
a = Q(0, 0)
b = Q(1, 1)
if a < b - a:
    pass

```
